## TCL-1 GENE AND PROTEIN AND RELATED METHODS AND COMPOSITIONS

This invention was made in part with government support under Grant number CA 39860 awarded by the National Institutes of Health. The government has certain rights in the invention.

### 1. INTRODUCTION

The present invention relates to nucleotide sequences of  
10 TCL-1 genes and amino acid sequences of their encoded  
proteins, as well as derivatives and analogs thereof and  
antibodies thereto. The present invention relates to the use  
of nucleotide sequences of TCL-1 genes and amino acid  
sequences of their encoded proteins, as well as derivatives  
15 and analogs thereof and antibodies thereto, as diagnostic and  
therapeutic reagents for the detection and treatment of  
disease states associated with chromosomal abnormalities. The  
present invention also relates to therapeutic compositions  
comprising TCL-1 proteins, derivatives or analogs thereof,  
20 antibodies thereto, nucleic acids encoding the TCL-1 proteins,  
derivatives or analogs, and TCL-1 antisense nucleic acid.

### 2. BACKGROUND OF THE INVENTION

There is a close association between particular  
25 chromosomal abnormalities, e.g., chromosomal translocations,  
inversions, and deletions, and certain types of malignancy  
indicating that such abnormalities may have a causative role  
in the cancer process. Chromosomal abnormalities may lead to  
gene fusion resulting in chimeric oncoproteins, such as is  
30 observed in the majority of the tumors involving the myeloid  
lineage. Alternatively, chromosomal abnormalities may lead to  
deregulation of protooncogenes by their juxtaposition to a  
regulatory element active in the hematopoietic cells, such as  
is observed in the translocation occurring in the lymphocytic  
35 lineage (Virgilio et al., 1993, Proc. Natl. Acad. Sci. USA  
90:9275-9279).

Non random chromosomal translocations are characteristic of most human hematopoietic malignancies (Haluska et al., 1987, Ann. Rev. Genet. 21:321-345) and may be involved in some solid tumors (Croce, 1987, Cell 49:155-156). In B and T cells, chromosomal translocations and inversions often occur as a consequence of mistakes during the normal process of recombination of the genes for immunoglobulins (Ig) or T-cell receptors (TCR). These rearrangements juxtapose enhancer elements of the Ig or TCR genes to oncogenes whose expression is then deregulated (Croce, 1987, Cell 49:155-156). In the majority of the cases, the rearrangements observed in lymphoid malignancies occur between two different chromosomes.

The *TCL-1* locus on chromosome 14 band q32.1 is frequently involved in the chromosomal translocations and inversions with the T-cell receptor genes observed in several post-thymic types of T-cell leukemias and lymphomas, including T-prolymphocytic leukemias (T-PLL) (Brito-Babapulle and Catovsky, 1991, Cancer Genet. Cytogenet. 55:1-9), acute and chronic leukemias associated with the immunodeficiency syndrome ataxia-telangiectasia (AT) (Russo et al., 1988, Cell 53:137-144; Russo et al., 1989, Proc. Natl. Acad. Sci. USA 86:602-606), and adult T-cell leukemia (Virgilio et al., 1993, Proc. Natl. Acad. Sci. USA 90:9275-9279).

Rearrangements of the *TCL-1* locus at chromosome 14q32.1 are unique, in that the other locus involved in these rearrangements, namely the *TCR α/δ* locus, is also on chromosome 14 at subband q11 (Croce et al., 1985, Science 227:1044-1047; Isobe et al., 1988, Proc. Natl. Acad. Sci. USA 85:3933-3937). For this reason, the rearrangements observed cytogenetically are either chromosomal inversions, inv(14) (q11;q32), involving only one of the chromosomes 14 or translocations involving both chromosomes 14 such as the t(14;14) (q11;q32), or more rarely, the t(7;14) (q35;q32) involving the *TCR β* locus at 7q35 (Isobe et al., 1988, Proc. Natl. Acad. Sci. USA 85:3933-3937). Several of the breakpoints at 14q32.1 involved in these translocations have been cloned and characterized (Russo et al., 1988, Cell

53:137-144; Baer et al., 1987, Proc. Natl. Acad. Sci. USA 84:9069-9073; Mengle-Gaw et al., 1987, EMBO J. 6:2273-2280; Bertness et al., 1990, Cancer Genet. Cytogenet. 44:47-54).

The *TCL-1* locus, a chromosomal region of approximately 5 350 kb as determined by placement of translocation breakpoints on the long range genomic map, has recently been cloned (Virgilio et al., 1993, Proc. Natl. Acad. Sci. USA 90:9275-9279). The involvement of such a large region in translocation events suggests that activation of the putative 10 *TCL-1* gene may occur from a distance of many kilobases, as previously observed for the *BCL-1/CCND1* gene in mantle cell lymphoma (Tsujimoto et al., 1984, Science 224:1403-1406; Rosenberg et al., 1991, Proc. Natl. Acad. Sci. USA 88:9638-9642; Withers et al., 1991, Mol. Cell. Biol. 11:4846-4853; 15 Motokura and Arnold, 1993, Genes, Chrom. & Cancer 7:89-95) and the *MYC* oncogene in Burkitt lymphoma (Dalla-Favera et al., 1982, Proc. Natl. Acad. Sci. USA 79:7824-7827; Nishikura et al., 1983, Proc. Natl. Acad. Sci. USA 80:4822-4826) and in acute T-cell leukemia (Erikson et al., 1986, Science 232:884-20 886).

There remains an unfulfilled need to isolate and characterize the *TCL-1* gene associated with chromosomal abnormalities, e.g., chromosomal translocations, inversions and deletions, for use as a diagnostic and therapeutic/ 25 prophylactic reagent in the detection, treatment, and prevention of diseases, such as T-cell leukemias and lymphomas, associated with such chromosomal abnormalities.

Citation of references hereinabove shall not be construed as an admission that such references are prior art to the 30 present invention.

### 3. SUMMARY OF THE INVENTION

The present invention relates to nucleotide sequences of *TCL-1* genes, and amino acid sequences of their encoded *TCL-1* 35 proteins, as well as derivatives and analogs thereof, and antibodies thereto. The present invention further relates to nucleic acids hybridizable to or complementary to the

foregoing nucleotide sequences as well as equivalent nucleic acid sequences encoding a TCL-1 protein.

The present invention also relates to expression vectors encoding a TCL-1 protein, derivative or analog thereof, as well as host cells containing the expression vectors encoding the TCL-1 protein, derivative or analog thereof. As used herein, "TCL-1" shall be used with reference to the TCL-1 gene, whereas "TCL-1" shall be used with reference to the protein product of the TCL-1 gene.

10 The present invention further relates to the use of nucleotide sequences of TCL-1 genes and amino acid sequences of their encoded TCL-1 proteins as diagnostic reagents or in the preparation of diagnostic agents useful in the detection of disease states, such as T-cell leukemias, associated with  
15 chromosomal abnormalities, in particular at 14q32.1, and/or increased levels of expression of the TCL-1 protein. The invention further relates to the use of nucleotide sequences of TCL-1 genes and amino acid sequences of their encoded TCL-1 proteins as therapeutic/prophylactic agents in the  
20 treatment/prevention of disease states, such as T-cell leukemias, associated with chromosomal abnormalities, in particular at 14q32.1, and/or increased levels of expression of the TCL-1 protein.

The present invention provides a novel TCL-1 gene  
25 sequence that is preferentially expressed early in T and B lymphocyte differentiation pathways. The TCL-1 gene resides in a region of approximately 160 kb between two clusters of breakpoints on the TCL-1 locus, clusters of inversions on the centromeric side and clusters of simple balanced  
30 translocations on the telomeric side.

As described herein, the TCL-1 gene codes for a 1.3 kb transcript that is expressed only in restricted subsets of cells within the lymphoid lineage and expressed at high levels in leukemic cells carrying a t(14;14)(q11;q32) chromosome  
35 translocation or a inv(14)(q11;q32) chromosome inversion.

The TCL-1 gene and protein sequences disclosed herein, and antibodies thereto, may be used in assays to diagnose T-

cell leukemias and lymphomas associated with chromosomal abnormalities, and/or increased expression of TCL-1 protein, such as T-prolymphocytic leukemias (T-PLL), acute and chronic leukemias associated with ataxia-telangiectasia (AT), and  
5 adult T-cell leukemia, by detecting or measuring TCL-1 mRNA in or from a patient sample or by detecting or measuring levels of TCL-1 protein from a patient sample. For example, a TCL-1 sequence may be used in a Northern blot hybridization assay of RNA from biopsied or autopsied cells or tissues to diagnose  
10 disease.

The TCL-1 protein, or derivatives or analogs thereof, disclosed herein, may be used for the production of anti-TCL-1 antibodies which antibodies may be useful diagnostically in immunoassays for the detection or measurement of TCL-1 protein  
15 in a patient sample. Anti-TCL-1 antibodies may be used, for example, for the diagnostic detection or measurement of TCL-1 protein in biopsied cells and tissues.

Also disclosed herein are methods of treatment of diseases or conditions associated with chromosomal  
20 abnormalities and/or increased expression of TCL-1 proteins. Abnormalities of chromosome 14, such as inversions and translocations, particularly at 14q32.1, are associated with T-cell leukemias and lymphomas. TCL-1 gene sequences and their protein products may be used therapeutically in the  
25 treatment of disease states associated with chromosome 14 abnormalities. Anti-TCL-1 antibodies may be used therapeutically, for example, in neutralizing the activity of an overexpressed TCL-1 protein associated with disease.

Oligonucleotide sequences, including antisense RNA and  
30 DNA molecules and ribozymes, designed to inhibit the transcription or translation of TCL-1 mRNA, may be used therapeutically in the treatment of disease states associated with increased expression of TCL-1.

Proteins, peptides and organic molecules capable of  
35 modulating activity of TCL-1 may be used therapeutically in the treatment of disease states associated with aberrant expression of TCL-1.

The present invention also relates to therapeutic compositions comprising TCL-1 proteins, derivatives or analogs thereof, antibodies thereto, nucleic acids encoding the TCL-1 proteins, derivatives or analogs, and TCL-1 antisense nucleic acid.

The present invention also relates to methods of production of the TCL-1 proteins, derivatives and analogs, such as, for example, by recombinant means.

In particular embodiments of the invention described by way of Examples 6 and 7 herein, a human *TCL-1* sequence is disclosed and shown to be specifically over-expressed in various T-cell malignancies.

#### 4. DESCRIPTION OF THE FIGURES

FIGURES 1A AND 1B: Genomic and cDNA organization of the *TCL-1* gene. 1A. Genomic organization of the *TCL-1* locus on chromosome 14q32.1. Vertical bars refers to cloned breakpoints in the literature (see Virgilio et al., 1993, Proc. Natl. Acad. Sci. USA 90:9275-9279). Restriction sites are given for BssH II (B), Cla I (C), Eag I (E), Sfi (F), Ksp I (K), Mlu I (M), Not I (N), Nru I (R), Ecor I (R1), Sal I(S), Hind III (H) and BamH I (H1). P1 clones 7-4 and 20-21, covering the 140 kb region between the two clusters of cloned breakpoints, are shown by horizontal bars. Filled boxes represent probes used for RNA screening. Enlarged is shown a SalI-HindIII genomic fragment with the organization of the four exons of the *TCL-1* gene. 1B. *TCL-1* cDNA structure, open box represents 5' untranslated region, filled box represent encoding sequence and the 3' untranslated region (UTR) is shown in diagonal stripes.

#### 5. DETAILED DESCRIPTION OF THE INVENTION

The present invention relates to nucleotide sequences of *TCL-1* genes and amino acid sequences of their encoded *TCL-1* proteins, as well as derivatives and analogs thereof, and antibodies thereto.

The present invention further relates to the use of *TCL-1* genes and their encoded proteins or derivatives or analogs thereof, and antibodies thereto, in assays for the detection and in treatment/prevention of disease states associated with chromosomal abnormalities and/or increased expression of *TCL-1*. The present invention also relates to therapeutic compositions comprising *TCL-1* proteins, derivatives or analogs thereof, antibodies thereto, nucleic acids encoding the *TCL-1* proteins, derivatives or analogs, and *TCL-1* antisense nucleic acid.

The *TCL-1* gene sequence can be from one of many different species, including but not limited to, mammalian, bovine, ovine, porcine, equine, rodent and human, in naturally occurring-sequence or in variant form, or from any source, whether natural, synthetic, or recombinant. In a specific embodiment described herein, the *TCL-1* gene sequence is a human sequence. The *TCL-1* protein can be that present in one of many different species, including but not limited to, mammalian, bovine, ovine, porcine, equine, rodent and human, in naturally occurring or variant form, or from any source, whether natural, synthetic, or recombinant. In specific embodiment described herein, the *TCL-1* protein is a human protein.

As defined herein, a *TCL-1* derivative may be a fragment or amino acid variant of the *TCL-1* sequence shown in Figure 3A as long as the fragment or amino acid variant is capable of

displaying one or more biological activities associated with a full-length TCL-1 protein. Such biological activities include but are not limited to antigenicity, i.e., the ability to bind to an anti-TCL-1 antibody, and immunogenicity, i.e., the ability to generate an antibody which is capable of binding a TCL-1 protein. The invention provides fragments of a TCL-1 protein consisting of at least 10 amino acids, or of at least 25 amino acids, or of at least 50 amino acids, or of at least 114 amino acids. Nucleic acids encoding such derivatives or analogs are also within the scope of the invention. A preferred TCL-1 protein variant is one sharing at least 70% amino acid sequence homology, a particularly preferred TCL-1 protein variant is one sharing at least 80% amino acid sequence homology and another particularly preferred TCL-1 protein variant is one sharing at least 90% amino acid sequence homology to the naturally occurring TCL-1 protein over at least 25, at least 50, at least 75 or at least 100 contiguous amino acids of the TCL-1 amino acid sequence. As used herein, amino acid sequence homology refers to amino acid sequences having identical amino acid residues or amino acid sequences containing conservative changes in amino acid residues. In another embodiment, a TCL-1 homologous protein is one that shares the foregoing percentages of sequences identical with the naturally occurring TCL-1 protein over the recited lengths of amino acids.

TCL-1 is a gene located in the region of chromosome 14q32.1 that is located in a region banded by two clusters of breakpoints. As is shown *infra* in Section 7, TCL-1 is preferentially expressed early in both the T and B lymphocyte differentiation pathways. As demonstrated *infra* in Section 7, high expression levels of TCL-1 are shown to occur in independent cases of T-PLL carrying an inversion of chromosome 14. Accordingly, the detection of TCL-1 mRNA in patient samples such as biopsied cells and tissues can be used as an indicator of the presence of T-cell leukemias and lymphomas associated with certain chromosome 14 abnormalities and/or increased expression of TCL-1 protein. Also, the TCL-1 amino

acid sequences of the present invention can be used to generate antibodies useful in immunoassays for the detection or measurement of TCL-1 in patient samples. Such anti-TCL-1 antibodies can be used in diagnostic immunoassays, for the  
5 detection or measurement of increased levels of TCL-1 associated with T-cell leukemias and lymphomas.

The present invention is illustrated *infra*, in part, by way of examples disclosing the cloning and sequencing of human TCL-1 and its increased expression in various T-cell  
10 malignancies.

### 5.1. The TCL-1 Coding Sequences

TCL-1 cDNA, genomic sequences and sequences complementary thereto are provided by the present invention. In a specific  
15 embodiment herein, a TCL-1 cDNA sequence is provided, thus lacking any introns. Also included within the scope of the present invention are polynucleotide sequences of TCL-1 cDNA consisting of at least 8 nucleotides, at least 15 nucleotides, at least 25 nucleotides, at least 50 nucleotides, at least 100  
20 nucleotides, at least 200 nucleotides, at least 387 nucleotides, or at least 1324 nucleotides. In a specific embodiment herein, a TCL-1 genomic sequence is provided, thus containing introns. Also included within the scope of the present invention are polynucleotides of TCL-1 genomic DNA  
25 consisting of not more than 5 kilobases, of not more than 10 kilobases, not more than 25 kilobases, not more than 50 kilobases, or not more than 70 kilobases.

The full length cDNA sequence for human TCL-1 is depicted in Figure 3A (SEQ ID NO: 1). Figure 3B (SEQ ID NO: 3) depicts  
30 a 5' genomic (noncoding) sequence of a human TCL-1 gene from nucleotide numbers 1 - 496. Figures 9A-9D (SEQ ID NO: 5) depicts the entire genomic sequence of the TCL-1 gene. Sequence analysis of the TCL-1 cDNA of Figure 3A reveals an open reading frame of 342 nucleotides with a starting ATG  
35 codon at position 46, located within a Kozak consensus sequence, and with a stop codon at position 388, potentially encoding a protein of 114 amino acids with a predicted

molecular weight of 13.5 kDa. This sequence when subcloned in a procaryotic expression vector encodes a 14kDa protein, that contains a casein kinase II phosphorylation site (MAECPTLGAVTDH) (a portion of SEQ ID NO: 2) starting at amino acid position 6. As disclosed *infra*, see Section 6.2.3, a rabbit polyclonal anti-TCL-1 antibody has been generated that is able to immunoprecipitate naturally occurring TCL-1 protein from lymphoid and leukemia cells expressing TCL-1 mRNA confirming that the open reading frame starting with the ATG at position 46 is able to translate naturally occurring TCL-1 protein.

In accordance with the present invention, any polynucleotide sequence which encodes the amino acid sequence of a TCL-1 gene product can be used to generate recombinant molecules which direct the expression of TCL-1. Included within the scope of the present invention are polynucleotide sequences of TCL-1 consisting of at least 8 nucleotides that are useful as probes or primers (*i.e.*, a hybridizable portion) in the detection of TCL-1. In a particular embodiment of the present invention, TCL-1 primers p9A- TGCTGCCAGATGACTGATGT (SEQ ID NO:6) and Rev III CAAATGGAATCCTCCTTGGC (SEQ ID NO:7) were used to amplify TCL-1 nucleic acid from bone marrow B-cells, T-cells lines, peripheral blood lymphocytes (PBL), PHA stimulated PBL and thymus cells. In another embodiment of the present invention, amplification of DNA from patients with T-PLL was carried out with primers Daudi unil-AGGCCTATGACCCCCACC (SEQ ID NO:8) and Daudi rev2-CATTCCTCCCAGACCCCA (SEQ ID NO:9). All primers disclosed herein are listed in 5' to 3' orientation.

In a specific embodiment disclosed herein, the invention relates to the nucleic acid sequence of the human TCL-1 gene. In a preferred, but not limiting, aspect of the invention, a human TCL-1 cDNA sequence is that present in plasmid PA11.5 as deposited with the ATCC and assigned ATCC Accession Number \_\_\_\_\_. Such a sequence can be cloned and sequenced, for example, as described in Section 6, *infra*. The invention also relates to nucleic acid sequences hybridizable or complementary to the

foregoing sequences or equivalent to the foregoing sequences in that the equivalent nucleic acid sequences also encode a TCL-1 protein product.

Nucleic acids encoding fragments and derivatives of *TCL-1* 5 are additionally described *infra*.

In a preferred aspect, polymerase chain reaction (PCR) is used to amplify the desired nucleic acid sequence in the library by using oligonucleotide primers representing known *TCL-1* sequences. Such primers are disclosed *infra* in Section 10 7 and may be used to amplify sequences of interest from an RNA or DNA source, preferably a cDNA library. PCR can be carried out, e.g., by use of a Perkin-Elmer Cetus thermal cycler and Taq polymerase (Gene Amp<sup>®</sup>). The DNA being amplified can include mRNA or cDNA or genomic DNA from any eukaryotic 15 species. One can choose to synthesize several different degenerate primers, for use in the PCR reactions. It is also possible to vary the stringency of hybridization conditions used in priming the PCR reactions, to allow for greater or lesser degrees of nucleotide sequence homology between the 20 *TCL-1* gene being cloned and the known *TCL-1* gene. Other means for primer dependent amplification of nucleic acids are known to those of skill in the art and can be used.

After successful amplification of a segment of a *TCL-1* gene (e.g., an allelic or polymorphic variant or species 25 homolog of a known *TCL-1* gene) that segment may be molecularly cloned and sequenced, and utilized as a probe to isolate a complete cDNA or genomic clone. This, in turn, will permit the determination of the gene's complete nucleotide sequence, the analysis of its expression, and the production of its 30 protein product for functional analysis, as described *infra*. In this fashion, additional genes encoding *TCL-1* proteins may be identified. Alternatively, the *TCL-1* gene of the present invention may be isolated through an exon trapping system, as is disclosed *infra*, in Section 6, using genomic DNA (Nehls et 35 al., 1994, Oncogene 9(8):2169-2175; Verna et al., 1993, Nucleic Acids Res. 21(22):5198:5202; and Auch et al., 1990, Nucleic Acids Res. 18(22):6743-6744).

Potentially, any eukaryotic cell can serve as the nucleic acid source for the molecular cloning of the *TCL-1* gene. The nucleic acid sequences encoding *TCL-1* can be isolated from, for example, human, porcine, bovine, feline, avian, equine, canine, rodent, as well as additional primate sources. The DNA may be obtained by standard procedures known in the art from, for example, cloned DNA (e.g., a DNA "library"), by chemical synthesis, by cDNA cloning, or by the cloning of genomic DNA, or fragments thereof, purified from a desired cell. (See, for example, Sambrook et al., 1989, *Molecular Cloning, A Laboratory Manual*, 2d Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York; Glover, D.M. (ed.), 1985, *DNA Cloning: A Practical Approach*, MRL Press, Ltd., Oxford, U.K. Vol. I, II.) A preferred source is cDNA of leukemic cells in which the leukemia is associated with a 14q32.1 chromosomal abnormality. Clones derived from genomic DNA may contain regulatory and intron DNA regions in addition to coding regions while clones derived from cDNA will contain only *TCL-1* exon sequences. In a particular embodiment of the present invention, a genomic sequence is one that is not more than 10 kilobases (kb), or not more than 20 kb, or not more than 50 kb or not more than 70 kb. Whatever the source, the gene should be molecularly cloned into a suitable vector for propagation of the gene. In a particular embodiment, a preferred source of nucleic acid for the isolation of *TCL-1* gene sequences is from pre B-cells.

In the molecular cloning of the gene from genomic DNA, DNA fragments are generated, some of which will encode the desired gene. The DNA may be cleaved at specific sites using various restriction enzymes. Alternatively, one may use DNase in the presence of manganese to fragment the DNA, or the DNA can be physically sheared, as for example, by sonication. The linear DNA fragments can then be separated according to size by standard techniques, including but not limited to, agarose and polyacrylamide gel electrophoresis and column chromatography.

Once the DNA fragments are generated, identification of the specific DNA fragment containing the desired gene may be accomplished in a number of ways. For example, a *TCL-1* gene of the present invention or its specific RNA, or a fragment thereof, such as a probe or primer, may be isolated and labeled and then used in hybridization assays to detect a generated *TCL-1* gene (Benton, W. and Davis, R., 1977, Science 196:180; Grunstein, M. And Hogness, D., 1975, Proc. Natl. Acad. Sci. USA 72:3961). Those DNA fragments sharing substantial sequence homology to the probe will hybridize under stringent conditions. The phrase "stringent conditions" as used herein refers to those hybridizing conditions that (1) employ low ionic strength and high temperature for washing, for example, 0.015 M NaCl/0.0015 M sodium citrate/0.1% SDS at 50°C.; (2) employ during hybridization a denaturing agent such as formamide, for example, 50% (vol/vol) formamide with 0.1% bovine serum albumin/0.1% Ficoll/0.1% polyvinylpyrrolidone/50 mM sodium phosphate buffer at pH 6.5 with 750 mM NaCl, 75 mM sodium citrate at 42°C; or (3) employ 50% formamide, 5 x SSC (0.75 M NaCl, 0.075 M sodium pyrophosphate, 5 x Denhardt's solution, sonicated salmon sperm DNA (50 g/ml), 0.1% SDS, and 10% dextran sulfate at 42°C, with washes at 42°C in 0.2 x SSC and 0.1% SDS.

It is also possible to identify the appropriate fragment by restriction enzyme digestion(s) and comparison of fragment sizes with those expected according to a known restriction map. Further selection can be carried out on the basis of the properties of the gene. Alternatively, the presence of the gene may be detected by assays based on the physical, chemical, or immunological properties of its expressed product. For example, cDNA clones, or genomic DNA clones which hybrid-select the proper mRNAs, can be selected which produce a protein that has similar or identical electrophoretic migration, isoelectric focusing behavior, proteolytic digestion maps, binding activity or antigenic properties as known for *TCL-1*. Alternatively, the *TCL-1* protein may be identified by binding of labeled antibody to

the putatively TCL-1 expressing clones, e.g., in an ELISA (enzyme-linked immunosorbent assay)-type procedure.

The *TCL-1* gene can also be identified by mRNA selection by nucleic acid hybridization followed by *in vitro* translation. In this procedure, fragments are used to isolate complementary mRNAs by hybridization. Such DNA fragments may represent available, purified *TCL-1* DNA of another *TCL-1* gene. Immunoprecipitation analysis or functional assays of the *in vitro* translation products of the isolated products of the isolated mRNAs identifies the mRNA and, therefore, the complementary DNA fragments that contain the desired sequences. In addition, specific mRNAs may be selected by adsorption of polysomes isolated from cells to immobilized antibodies specifically directed against *TCL-1* protein. A radiolabelled *TCL-1* cDNA can be synthesized using the selected mRNA (from the adsorbed polysomes) as a template. The radiolabelled mRNA or cDNA may then be used as a probe to identify the *TCL-1* DNA fragments from among other genomic DNA fragments.

Alternatives to isolating the *TCL-1* genomic DNA include, but are not limited to, chemically synthesizing the gene sequence itself from a known sequence or making cDNA to the mRNA which encodes the *TCL-1* protein. For example, RNA useful in cDNA cloning of the *TCL-1* gene can be isolated from cells which express *TCL-1*, e.g., pre-B acute lymphoblastic leukemia cells or endemic Burkitt's lymphoma cells which express cell surface IgM and do not secrete immunoglobulin. Other methods are known to those of skill in the art and are within the scope of the invention.

The identified and isolated gene can then be inserted into an appropriate cloning vector. A large number of vector-host systems known in the art may be used. Possible vectors include, but are not limited to, plasmids or modified viruses, but the vector system must be compatible with the host cell used. Such vectors include, but are not limited to, bacteriophages such as lambda derivatives, or plasmids such as PBR322 or pUC plasmid derivatives. The insertion into a

cloning vector can, for example, be accomplished by ligating the DNA fragment into a cloning vector which has complementary cohesive termini. However, if the complementary restriction sites used to fragment the DNA are not present in the cloning  
5 vector, the ends of the DNA molecules may be enzymatically modified. Alternatively, any site desired may be produced by ligating nucleotide sequences (linkers) onto the DNA termini; these ligated linkers may comprise specific chemically synthesized oligonucleotides encoding restriction endonuclease  
10 recognition sequences. In an alternative method, the cleaved vector and TCL-1 gene may be modified by homopolymeric tailing. Recombinant molecules can be introduced into host cells via transformation, transfection, infection, electroporation, or other methods known to those of skill in  
15 the art, so that many copies of the gene sequence are generated.

In an alternative method, the desired gene may be identified and isolated after insertion into a suitable cloning vector in a "shot gun" approach. Enrichment for the  
20 desired gene, for example, by size fractionization, can be done before insertion into the cloning vector.

In specific embodiments, transformation of host cells with recombinant DNA molecules that incorporate the isolated TCL-1 gene, cDNA, or synthesized DNA sequence enables  
25 generation of multiple copies of the gene. Thus, the gene may be obtained in large quantities by growing transformants, isolating the recombinant DNA molecules from the transformants and, when necessary, retrieving the inserted gene from the isolated recombinant DNA.

30 Oligonucleotides containing a portion of the TCL-1 coding or non-coding sequences, or which encode a portion of the TCL-1 protein (e.g., primers for use in PCR) can be synthesized by standard methods commonly known in the art. Such oligonucleotides preferably have a size in the range of 8  
35 to 25 nucleotides. In a particular embodiment herein, such oligonucleotides have a size in the range of 15 to 25 nucleotides or 18 to 25 nucleotides.

### 5.2. Expression of the TCL-1 Gene

In accordance with the present invention, polynucleotide sequences coding for a TCL-1 protein, derivative, e.g. fragment, or analog thereof, can be inserted into an appropriate expression vector, i.e., a vector which contains the necessary elements for the transcription and translation of the inserted protein-coding sequence, for the generation of recombinant DNA molecules that direct the expression of a TCL-1 protein. Such TCL-1 polynucleotide sequences, as well as other polynucleotides or their complements, may also be used in nucleic acid hybridization assays, Southern and Northern blot analysis, etc. In a specific embodiment, a human TCL-1 gene, or a sequence encoding a functionally active portion of a human TCL-1 gene is expressed. In yet another embodiment, a derivative or fragment of a human TCL-1 gene is expressed.

Due to the inherent degeneracy of the genetic code, other DNA sequences which encode substantially the same or a functionally equivalent TCL-1 amino acid sequence, is within the scope of the invention. Such DNA sequences include those which are capable of hybridizing to the human TCL-1 sequence under stringent conditions.

Altered DNA sequences which may be used in accordance with the invention include deletions, additions or substitutions of different nucleotide residues resulting in a sequence that encodes the same or a functionally equivalent gene product. The gene product itself may contain deletions, additions or substitutions of amino acid residues within an TCL-1 sequence, which result in a silent change thus producing a functionally equivalent TCL-1 protein. Such amino acid substitutions may be made on the basis of similarity in polarity, charge, solubility, hydrophobicity, hydrophilicity, and/or the amphipathic nature of the residues involved. For example, negatively charged amino acids include aspartic acid and glutamic acid; positively charged amino acids include lysine and arginine; amino acids with uncharged polar head groups having similar hydrophilicity values include the following: leucine, isoleucine, valine; glycine, alanine;

asparagine, glutamine; serine, threonine; phenylalanine, tyrosine.

The DNA sequences of the invention may be engineered in order to alter a TCL-1 coding sequence for a variety of ends including but not limited to alterations which modify processing and expression of the gene product. For example, mutations may be introduced using techniques which are well known in the art, e.g., site-directed mutagenesis, to insert new restriction sites, to alter phosphorylation, etc.

10 In another embodiment of the invention, a TCL-1 gene sequence or a derivative thereof is ligated to a non-TCL-1 sequence to encode a chimeric fusion protein. A fusion protein may also be engineered to contain a cleavage site located between a TCL-1 sequence and the non-TCL-1 protein  
15 sequence, so that the TCL-1 protein may be cleaved away from the non-TCL-1 moiety. In a specific embodiment, the TCL-1 amino acid sequence present in the fusion protein consists of at least 10 contiguous amino acids, at least 25 contiguous amino acids, at least 50 contiguous amino acids, at least 75  
20 contiguous amino acids, at least 100 contiguous amino acids, or at least 114 amino acids of the TCL-1 protein sequence.

In an alternate embodiment of the invention, the coding sequence of a TCL-1 is synthesized in whole or in part, using chemical methods well known in the art. See, for example,  
25 Caruthers et al., 1980, Nuc. Acids Res. Symp. Ser. 7:215-233; Crea and Horn, 1980, Nuc. Acids Res. 9(10):2331; Matteucci and Caruthers, 1980, Tetrahedron Letters 21:719; and Chow and Kempe, 1981, Nuc. Acids Res. 9(12):2807-2817. Alternatively, the protein itself could be produced using chemical methods to  
30 synthesize an TCL-1 amino acid sequence in whole or in part. For example, peptides can be synthesized by solid phase techniques, cleaved from the resin, and purified by preparative high performance liquid chromatography. (e.g., see Creighton, 1983, Proteins Structures And Molecular  
35 Principles, W.H. Freeman and Co., N.Y. pp. 50-60). The composition of the synthetic peptides may be confirmed by amino acid analysis or sequencing (e.g., the Edman degradation

procedure; see Creighton, 1983, Proteins, Structures and Molecular Principles, W.H. Freeman and Co., N.Y., pp. 34-49.

In order to express a biologically active TCL-1 protein or derivative thereof, a polynucleotide sequence encoding a  
5 TCL-1 protein, or a derivative thereof, is inserted into an appropriate expression vector, i.e., a vector which contains the necessary elements for the transcription and translation of the inserted coding sequence. The TCL-1 gene products as well as host cells or cell lines transfected or transformed  
10 with recombinant TCL-1 expression vectors can be used for a variety of purposes. These include but are not limited to generating antibodies (i.e., monoclonal or polyclonal) that immunospecifically bind a TCL-1 protein. Anti-TCL-1 antibodies can be used in detecting or measuring levels of a  
15 TCL-1 protein in patient samples.

### 5.3. Expression Systems

Methods which are well known to those skilled in the art can be used to construct expression vectors containing a TCL-1  
20 coding sequence and appropriate transcriptional/translational control signals. These methods include *in vitro* recombinant DNA techniques, synthetic techniques and *in vivo* recombination/genetic recombination. See, for example, the techniques described in Sambrook et al., 1989, Molecular  
25 Cloning, A Laboratory Manual 2d ed., Cold Spring Harbor Laboratory, N.Y. and Ausubel et al., 1989, Current Protocols in Molecular Biology, Greene Publishing Associates and Wiley Interscience, N.Y.

A variety of host-expression vector systems may be  
30 utilized to express a TCL-1 coding sequence. These include but are not limited to microorganisms such as bacteria transformed with recombinant bacteriophage DNA, plasmid DNA or cosmid DNA expression vectors containing an TCL-1 coding sequence; yeast transformed with recombinant yeast expression  
35 vectors containing an TCL-1 coding sequence; insect cell systems infected with recombinant virus expression vectors (e.g., baculovirus) containing an TCL-1 coding sequence; plant

cell systems infected with recombinant virus expression vectors (e.g., cauliflower mosaic virus, CaMV; tobacco mosaic virus, TMV) or transformed with recombinant plasmid expression vectors (e.g., Ti plasmid) containing an TCL-1 coding sequence; or animal cell systems. The expression elements of these systems vary in their strength and specificities. Depending on the host/vector system utilized, any of a number of suitable transcription and translation elements, including constitutive and inducible promoters, may be used in the expression vector. For example, when cloning in bacterial systems, inducible promoters such as pL of bacteriophage  $\lambda$ , plac, ptrp, ptac (ptrp-lac hybrid promoter) and the like may be used; when cloning in insect cell systems, promoters such as the baculovirus polyhedrin promoter may be used; when cloning in plant cell systems, promoters derived from the genome of plant cells (e.g., heat shock promoters; the promoter for the small subunit of RUBISCO; the promoter for the chlorophyll a/b binding protein) or from plant viruses (e.g., the 35S RNA promoter of CaMV; the coat protein promoter of TMV) may be used; when cloning in mammalian cell systems, promoters derived from the genome of mammalian cells (e.g., metallothionein promoter) or from mammalian viruses (e.g., the adenovirus late promoter; the vaccinia virus 7.5 K promoter) may be used; when generating cell lines that contain multiple copies of an TCL-1 DNA, SV40-, BPV- and EBV-based vectors may be used with an appropriate selectable marker.

In bacterial systems, a number of expression vectors may be advantageously selected depending upon the use intended for the TCL-1 protein expressed. For example, when large quantities of TCL-1 protein are to be produced for the generation of antibodies, vectors which direct the expression of high levels of fusion protein products that are readily purified may be desirable. Such vectors include but are not limited to the *E. coli* expression vector pUR278 (Ruther et al., 1983, EMBO J. 2:1791), in which the TCL-1 coding sequence may be ligated into the vector in frame with the lac Z coding region so that a hybrid AS-lac Z protein is produced; pIN

vectors (Inouye & Inouye, 1985, Nucleic acids Res. 13:3101-3109; Van Heeke & Schuster, 1989, J. Biol. Chem. 264:5503-5509); and the like. pGEX vectors may also be used to express foreign polypeptides as fusion proteins with glutathione S-transferase (GST). In general, such fusion proteins are soluble and can easily be purified from lysed cells by adsorption to glutathione-agarose beads followed by elution in the presence of free glutathione. The pGEX vectors are designed to include thrombin or factor Xa protease cleavage sites so that the cloned polypeptide of interest can be released from the GST moiety.

In yeast, a number of vectors containing constitutive or inducible promoters may be used. For a review see, Current Protocols in Molecular Biology, Vol. 2, 1988, Ed. Ausubel et al., Greene Publish. Assoc. & Wiley Interscience, Ch. 13; Grant et al., 1987, Expression and Secretion Vectors for Yeast, in Methods in Enzymology, Ed. Wu & Grossman, 1987, Acad. Press, N.Y. 153:516-544; Glover, 1986, DNA Cloning, Vol. II, IRL Press, Wash., D.C., Ch. 3; and Bitter, 1987, Heterologous Gene Expression in Yeast, Methods in Enzymology, Eds. Berger & Kimmel, Acad. Press, N.Y. 152:673-684; and The Molecular Biology of the Yeast Saccharomyces, 1982, Eds. Strathern et al., Cold Spring Harbor Press, Vols. I and II.

In cases where plant expression vectors are used, the expression of an *TCL-1* coding sequence may be driven by any of a number of promoters. For example, viral promoters such as the 35S RNA and 19S RNA promoters of CaMV (Brisson et al., 1984, Nature 310:511-514), or the coat protein promoter of TMV (Takamatsu et al., 1987, EMBO J. 6:307-311) may be used; alternatively, plant promoters such as the small subunit of RUBISCO (Coruzzi et al., 1984, EMBO J. 3:1671-1680; Broglie et al., 1984, Science 224:838-843); or heat shock promoters, e.g., soybean hsp17.5-E or hsp17.3-B (Gurley et al., 1986, Mol. Cell. Biol. 6:559-565) may be used. These constructs can be introduced into plant cells using Ti plasmids, Ri plasmids, plant virus vectors, direct DNA transformation, microinjection, electroporation, etc. For reviews of such

techniques see, for example, Weissbach & Weissbach, 1988, Methods for Plant Molecular Biology, Academic Press, NY, Section VIII, pp. 421-463; and Grierson & Corey, 1988, Plant Molecular Biology, 2d Ed., Blackie, London, Ch. 7-9.

5       An alternative expression system which could be used to express a TCL-1 gene is an insect system. In one such system, *Autographa californica* nuclear polyhedrosis virus (AcNPV) is used as a vector to express foreign genes. The virus grows in *Spodoptera frugiperda* cells. A TCL-1 coding sequence may be  
10       cloned into non-essential regions (for example the polyhedrin gene) of the virus and placed under control of an AcNPV promoter (for example, the polyhedrin promoter). Successful insertion of a TCL-1 coding sequence will result in inactivation of the polyhedrin gene and production of non-  
15       occluded recombinant virus (i.e., virus lacking the proteinaceous coat coded for by the polyhedrin gene). These recombinant viruses are then used to infect *Spodoptera frugiperda* cells in which the inserted gene is expressed. (e.g., see Smith et al., 1983, J. Virol. 46:584; Smith, U.S.  
20       Patent No. 4,215,051).

      In mammalian host cells, a number of viral based expression systems may be utilized. In cases where an adenovirus is used as an expression vector, a TCL-1 coding sequence may be ligated to an adenovirus  
25       transcription/translation control complex, e.g., the late promoter and tripartite leader sequence. This chimeric gene may then be inserted in the adenovirus genome by in vitro or in vivo recombination. Insertion in a non-essential region of the viral genome (e.g., region E1 or E3) will result in a  
30       recombinant virus that is viable and capable of expressing a TCL-1 in infected hosts. (e.g., see Logan & Shenk, 1984, Proc. Natl. Acad. Sci. USA 81:3655-3659). Alternatively, the vaccinia 7.5 K promoter may be used. (See, e.g., Mackett et al., 1982, Proc. Natl. Acad. Sci. USA 79:7415-7419; Mackett et  
35       al., 1984, J. Virol. 49:857-864; Panicali et al., 1982, Proc. Natl. Acad. Sci. USA 79:4927-4931).

Specific initiation signals may also be required for efficient translation of an inserted *TCL-1* coding sequences. These signals include the ATG initiation codon and adjacent sequences. In cases where an entire *TCL-1* gene, including its own initiation codon and adjacent sequences, is inserted into the appropriate expression vector, no additional translational control signals may be needed. However, in cases where only a portion of a *TCL-1* coding sequence is inserted, lacking the 5' end, exogenous translational control signals, including the ATG initiation codon, must be provided. Furthermore, the initiation codon must be in phase with the reading frame of a *TCL-1* coding sequence to ensure translation of the entire insert. These exogenous translational control signals and initiation codons can be of a variety of origins, both natural and synthetic. The efficiency of expression may be enhanced by the inclusion of appropriate transcription enhancer elements, transcription terminators, etc. (see Bittner et al., 1987, Methods in Enzymol. 153:516-544).

In addition, a host cell strain may be chosen which modulates the expression of the inserted sequences, or modifies and processes the gene product in the specific fashion desired. Such modifications (e.g., phosphorylation) and processing (e.g., cleavage) of protein products may be important for the function of the protein. Different host cells have characteristic and specific mechanisms for the post-translational processing and modification of proteins. Appropriate cells lines or host systems can be chosen to ensure the correct modification and processing of the foreign protein expressed. To this end, eukaryotic host cells which possess the cellular machinery for proper processing of the primary transcript, and phosphorylation of the gene product may be used. Such mammalian host cells include but are not limited to CHO, VERO, BHK, HeLa, COS, MDCK, 293, WI38, etc.

For long-term, high-yield production of recombinant proteins, stable expression is preferred. For example, cell lines which stably express a *TCL-1* protein may be engineered. Rather than using expression vectors which contain viral

origins of replication, host cells can be transformed with TCL-1 DNA controlled by appropriate expression control elements (e.g., promoter, enhancer, sequences, transcription terminators, polyadenylation sites, etc.), and a selectable marker. Following the introduction of foreign DNA, engineered cells may be allowed to grow for 1-2 days in an enriched media, and then are switched to a selective media. The selectable marker in the recombinant plasmid confers resistance to the selection and allows cells to stably integrate the plasmid into their chromosomes and grow to form foci which in turn can be cloned and expanded into cell lines. This method may advantageously be used to engineer cell lines which express a TCL-1 protein. The present invention provides a method for producing a recombinant TCL-1 protein comprising culturing a host cell transformed with a recombinant expression vector encoding a TCL-1 protein such that the TCL-1 protein is expressed by the cell and recovering the expressed TCL-1 protein.

A number of selection systems may be used, including but not limited to the herpes simplex virus thymidine kinase (Wigler et al., 1977, Cell 11:223), hypoxanthine-guanine phosphoribosyltransferase (Szybalska & Szybalski, 1962, Proc. Natl. Acad. Sci. USA 48:2026), and adenine phosphoribosyltransferase (Lowy et al., 1980, Cell 22:817) genes can be employed in tk-, hgprt- or aprt- cells, respectively. Also, antimetabolite resistance can be used as the basis of selection for dhfr, which confers resistance to methotrexate (Wigler et al., 1980, Natl. Acad. Sci. USA 77:3567; O'Hare et al., 1981, Proc. Natl. Acad. Sci. USA 78:1527); gpt, which confers resistance to mycophenolic acid (Mulligan & Berg, 1981, Proc. Natl. Acad. Sci. USA 78:2072); neo, which confers resistance to the aminoglycoside G-418 (Colberre-Garapin et al., 1981, J. Mol. Biol. 150:1); and hygromycin, which confers resistance to hygromycin (Santerre et al., 1984, Gene 30:147). Recently, additional selectable genes have been described, namely trpB, which allows cells to utilize indole in place of tryptophan; hisD, which allows

cells to utilize histinol in place of histidine (Hartman & Mulligan, 1988, Proc. Natl. Acad. Sci. USA 85:8047); and ODC (ornithine decarboxylase) which confers resistance to the ornithine decarboxylase inhibitor, 2-(difluoromethyl)-DL-  
5 ornithine, DFMO (McConlogue, L., 1987, In: Current Communications in Molecular Biology, Cold Spring Harbor Laboratory, Ed.).

10           **5.4. Identification of Transfectants or Transformants That Express TCL-1**

          The host cells which contain the coding sequence and which express the biologically active gene product may be identified by at least four general approaches; (a) DNA-DNA or DNA-RNA hybridization; (b) the presence or absence of "marker"  
15 gene functions; (c) assessing the level of transcription as measured by the expression of TCL-1 mRNA transcripts in the host cell; and (d) detection of the gene product as measured by immunoassay or by its biological activity.

          In the first approach, the presence of the TCL-1 coding  
20 sequence inserted in the expression vector can be detected by DNA-DNA or DNA-RNA hybridization using probes comprising nucleotide sequences that are homologous to the TCL-1 coding sequence, respectively, or portions or derivatives thereof.

          In the second approach, the recombinant expression  
25 vector/host system can be identified and selected based upon the presence or absence of certain "marker" gene functions (e.g., thymidine kinase activity, resistance to antibiotics, resistance to methotrexate, transformation phenotype, occlusion body formation in baculovirus, etc.). For example,  
30 if the human TCL-1 coding sequence is inserted within a marker gene sequence of the vector, recombinant cells containing the TCL-1 coding sequence can be identified by the absence of the marker gene function. Alternatively, a marker gene can be placed in tandem with a TCL-1 sequence under the control of  
35 the same or different promoter used to control the expression of the TCL-1 coding sequence. Expression of the marker in

response to induction or selection indicates expression of the TCL-1 coding sequence.

In the third approach, transcriptional activity of a TCL-1 gene can be assessed by hybridization assays. For example, RNA can be isolated and analyzed by Northern blot using a probe having sequence homology to a TCL-1 coding sequence or transcribed noncoding sequence or particular portions thereof. Alternatively, total nucleic acid of the host cell may be extracted and quantitatively assayed for hybridization to such probes.

In the fourth approach, the levels of a TCL-1 protein product can be assessed immunologically, for example by Western blots, immunoassays such as radioimmuno-precipitation, enzyme-linked immunoassays and the like.

15

#### 5.5. Purification of the Expressed Gene Product

Once a recombinant which expresses the TCL-1 gene sequence is identified, the gene product can be analyzed. This is achieved by assays based on the physical or functional properties of the product, including radioactive labelling of the product followed by analysis by gel electrophoresis, immunoassay, or other detection methods known to those of skill in the art.

Once the TCL-1 protein is identified, it may be isolated and purified by standard methods including chromatography (e.g., ion exchange, affinity, and sizing column chromatography), centrifugation, differential solubility, or by any other standard technique for the purification of proteins. The functional properties may be evaluated using any suitable assay.

Alternatively, once a TCL-1 protein produced by a recombinant is identified, the amino acid sequence of the protein can be deduced from the nucleotide sequence of the chimeric gene contained in the recombinant. As a result, the protein can be synthesized by standard chemical methods known in the art (e.g., see Hunkapiller et al., 1984, Nature 310:105-111).

In a specific embodiment of the present invention, such *TCL-1* proteins, whether produced by recombinant DNA techniques or by chemical synthetic methods, include but are not limited to those containing, as a primary amino acid sequence, all or 5 part of the amino acid sequence substantially as depicted in Figure 3A (SEQ ID NO:2), as well as fragments and other derivatives, and analogs thereof.

#### 5.6. Generation of Antibodies to *TCL-1*

10 According to the invention, *TCL-1* protein, its fragments or other derivatives, or analogs thereof, may be used as an immunogen to generate antibodies which recognize such an immunogen. Such antibodies include but are not limited to polyclonal, monoclonal, chimeric, single chain, Fab fragments, 15 and an Fab expression library. In a specific embodiment, antibodies to a human *TCL-1* protein are produced.

Various procedures known in the art may be used for the production of polyclonal antibodies to a *TCL-1* protein or derivative or analog. For the production of antibody, various 20 host animals can be immunized by injection with the native *TCL-1* protein, or a synthetic version, or derivative (e.g., fragment) thereof, including but not limited to rabbits, mice, rats, etc. Various adjuvants may be used to increase the immunological response, depending on the host species, and 25 including but not limited to Freund's (complete and incomplete), mineral gels such as aluminum hydroxide, surface active substances such as lysolecithin, pluronic polyols, polyanions, peptides, oil emulsions, keyhole limpet hemocyanins, dinitrophenol, and potentially useful human 30 adjuvants such as BCG (bacille Calmette-Guerin) and *corynebacterium parvum*.

In a specific example, the 14 kDa protein of the *TCL-1* gene expressed in bacteria was used to immunize rabbits against *TCL-1*. Such antibodies recognized the 14 kDa *TCL-1* 35 protein in a variety of leukemia and lymphoma cells by Western Blot and by immunoprecipitation.

For preparation of monoclonal antibodies directed toward a TCL-1 protein sequence or analog thereof, any technique which provides for the production of antibody molecules by continuous cell lines in culture may be used. For example, the hybridoma technique originally developed by Kohler and Milstein (1975, Nature 256:495-497), as well as the trioma technique, the human B-cell hybridoma technique (Kozbor et al., 1983, Immunology Today 4:72), and the EBV-hybridoma technique to produce human monoclonal antibodies (Cole et al., 1985, in Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, Inc., pp. 77-96). In an additional embodiment of the invention, monoclonal antibodies can be produced in germ-free animals utilizing recent technology (PCT/US90/02545). According to the invention, human antibodies may be used and can be obtained by using human hybridomas (Cote et al., 1983, Proc. Natl. Acad. Sci. USA 80:2026-2030) or by transforming human B cells with EBV virus in vitro (Cole et al., 1985, in Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, pp. 77-96). In fact, according to the invention, techniques developed for the production of "chimeric antibodies" (Morrison et al., 1984, Proc. Natl. Acad. Sci. USA 81:6851-6855; Neuberger et al., 1984, Nature 312:604-608; Takeda et al., 1985, Nature 314:452-454) by splicing the genes from a mouse antibody molecule specific for TCL-1 together with genes from a human antibody molecule of appropriate biological activity can be used; such antibodies are within the scope of this invention.

According to the invention, techniques described for the production of single chain antibodies (U.S. Patent No. 4,946,778) can be adapted to produce TCL-1-specific single chain antibodies. An additional embodiment of the invention utilizes the techniques described for the construction of Fab expression libraries (Huse et al., 1989, Science 246:1275-1281) to allow rapid and easy identification of monoclonal Fab fragments with the desired specificity for TCL-1 proteins, derivatives, or analogs.

Antibody fragments which contain the idiotype of the molecule can be generated by known techniques. For example, such fragments include but are not limited to: the  $F(ab')_2$  fragment which can be produced by pepsin digestion of the antibody molecule; the Fab' fragments which can be generated by reducing the disulfide bridges of the  $F(ab')_2$  fragment, and the Fab fragments which can be generated by treating the antibody molecule with papain and a reducing agent.

In the production of antibodies, screening for the desired antibody can be accomplished by techniques known in the art, e.g. ELISA (enzyme-linked immunosorbent assay). For example, to select antibodies which recognize a specific domain of a TCL-1 protein, one may assay generated hybridomas for a product which binds to a TCL-1 fragment containing such domain. For selection of an antibody specific to human TCL-1, one can select on the basis of positive binding to human TCL-1 and a lack of binding to, for example, mouse TCL-1.

The foregoing antibodies can be used in methods known in the art relating to the localization and activity of the protein sequences of the invention (e.g., see Section 5.7, *infra*), e.g., for imaging these proteins, measuring levels thereof in appropriate physiological samples, etc.

#### 5.7. Structure of the TCL-1 Gene and Protein

The structure of the TCL-1 gene and protein can be analyzed by various methods known in the art.

##### 5.7.1. Genetic Analysis

The cloned DNA or cDNA corresponding to the TCL-1 gene can be analyzed by methods including but not limited to Southern hybridization (Southern, E.M., 1975, J. Mol. Biol. 98:503-517), Northern hybridization (see, e.g., Freeman et al., 1983, Proc. Natl. Acad. Sci. USA 80:4094-4098), restriction endonuclease mapping (Maniatis, T., 1982, Molecular Cloning, A Laboratory, Cold Spring Harbor, New York), and DNA sequence analysis. Polymerase chain reaction (PCR; U.S. Patent Nos. 4,683,202, 4,683,195, and 4,889,818;

Gyllenstein et al., 1988, Proc. Natl. Acad. Sci. USA 85:7652-7656; Ochman et al., 1988, Genetics 120:621-623; Loh et al., 1989, Science 243:217-220) followed by Southern hybridization with a *TCL-1*-specific probe can allow the detection of the  
5 *TCL-1* gene in DNA from various cell types. In one embodiment, Southern hybridization may be used to determine the genetic linkage of *TCL-1*. PCR followed by hybridization assay can also be used to detect or measure *TCL-1* RNA or 14q32.1 chromosomal abnormalities. Northern hybridization analysis  
10 can be used to determine the expression levels of the *TCL-1* gene. Other assays are described in Section 5.8.1. Various cell types, at various states of development or activity can be tested for *TCL-1* expression. The stringency of the hybridization conditions for both Southern and Northern  
15 hybridization, or dot blots, can be manipulated to ensure detection of nucleic acids with the desired degree of relatedness to the specific *TCL-1* probe used.

Restriction endonuclease mapping can be used to roughly determine the genetic structure of the *TCL-1* gene.  
20 Restriction maps derived by restriction endonuclease cleavage can be confirmed by DNA sequence analysis.

DNA sequence analysis can be performed by any techniques known in the art, including but not limited to the method of Maxam and Gilbert (1980, Meth. Enzymol. 65:499-560), the  
25 Sanger dideoxy method (Sanger et al., 1977, Proc. Natl. Acad. Sci. USA 74:5463), the use of T7 DNA polymerase (Tabor and Richardson, U.S. Patent No. 4,795,699), or use of an automated DNA sequenator (e.g., Applied Biosystems, Foster City, CA). The cDNA sequence of a representative *TCL-1* gene comprises the  
30 sequence substantially as depicted in Figure 3A (SEQ ID NO: 1), and described in Section 6, *infra*.

#### 5.7.2. Protein Analysis

The amino acid sequence of the *TCL-1* protein can be  
35 derived by deduction from the DNA sequence, or alternatively, by direct sequencing of the protein, e.g., with an automated amino acid sequencer. The amino acid sequence of a

representative TCL-1 protein comprises the sequence substantially as depicted in Figure 3A (SEQ ID NO: 2), and detailed in Section 6, *infra*, with the representative mature protein that is shown by amino acid numbers 1-114.

5       The TCL-1 protein sequence can be further characterized by a hydrophilicity analysis (Hopp, T. and Woods, K., 1981, Proc. Natl. Acad. Sci. USA 78:3824). A hydrophilicity profile can be used to identify the hydrophobic and hydrophilic regions of the TCL-1 protein and the corresponding regions of  
10 the gene sequence which encode such regions.

Secondary structural analysis (Chou, P. and Fasman, G., 1974, Biochemistry 13:222) can also be done, to identify regions of the TCL-1 protein that assume specific secondary structures.

15       Manipulation, translation, and secondary structure prediction, as well as open reading frame prediction and plotting, can also be accomplished using computer software programs available in the art.

Other methods of structural analysis can also be  
20 employed. These include but are not limited to X-ray crystallography (Engstrom, A., 1974, Biochem. Exp. Biol. 11:7-13) and computer modeling (Fletterick, R. and Zoller, M. (eds.), 1986, Computer Graphics and Molecular Modeling, in Current Communications in Molecular Biology, Cold Spring  
25 Harbor Laboratory, Cold Spring Harbor, New York).

#### 5.8. Uses of TCL-1 and its TCL-1 Protein Product and Antibodies Thereto

Chromosomal translocations and inversions associated with  
30 the TCL-1 locus on chromosome 14, e.g., t(14:14)(q11;q32) chromosome translocation, inv(14)(q11;q32) chromosome inversion, and t(7:14)(q35;q32) chromosome translocation, are associated with several post-thymic types of T-cell leukemias, including, but not limited to, T-prolymphocytic leukemias (T-  
35 PLL) (Brito-Babapulle and Catovsky, 1991, Cancer Genet. Cytogenet. 55:1-9), acute and chronic leukemias associated with the immunodeficiency syndrome ataxia-telangiectasia (AT)

(Russo et al., 1988, Cell 53:137-144; Russo et al., 1989, Proc. Natl. Acad. Sci. USA 86:602-606), and adult T-cell leukemia (Virgilio et al., 1993, PNAS 90:9275-9279). In some cases of AT-associated translocations, in T-cell leukemia and lymphoma involving the 14q32.1 band, clonal expansion of cells carrying abnormalities in 14q32.1 have been documented in some cases prior to the development of overt malignancy (Russo, et al. (1988) Cell vol. 53, pg. 137-144). Therefore, a TCL-1 polynucleotide, its TCL-1 protein product and antibodies thereto can be used for diagnostic and/or therapeutic/prophylactic purposes for the above described diseases, as well as other disorders associated with chromosomal translocations and inversions associated with the TCL-1 locus and/or, increased expression of TCL-1 RNA or protein. A TCL-1 polynucleotide, its TCL-1 protein product and antibodies thereto may be used for therapeutic/prophylactic purposes alone or in combination with other therapeutics useful in the treatment of T-cell leukemias. Such molecules can also be used in diagnostic assays, such as immunoassays, to detect, prognose, diagnose, or monitor various conditions, diseases, and disorders associated with TCL-1 gene expression or monitor the treatment thereof. Accordingly, in specific embodiments, T-cell malignancies or premalignant changes in such tissues is diagnosed by detecting increased TCL-1 expression in patient samples relative to the level of TCL-1 expression in an analogous non-malignant sample (from the patient or another person, as determined experimentally or as is known as a standard level in such samples). For diagnostic purposes, a TCL-1 polynucleotide may be used to detect TCL-1 gene expression or increased TCL-1 gene expression in disease states, such as, T-cell leukemias and lymphomas. For therapeutic purposes, a TCL-1 protein can be used to make anti-TCL-1 antibodies that may neutralize the activity of TCL-1. Included within the scope of the present invention are oligonucleotide sequences, that include antisense RNA and DNA molecules and ribozymes, that function to inhibit expression of a TCL-1 RNA or protein.

### 5.8.1. Diagnostic Uses

As illustrated *infra*, the *TCL-1* gene sequence is associated with disease states associated with chromosome 14 translocations and inversions around the *TCL-1* locus, is preferentially expressed early in T and B lymphocyte differentiation and demonstrates a high level of expression in cells from patients diagnosed with T-PLL carrying an inversion of chromosome 14, *inv(14)(q11;q32)* or patients carrying a *t(14:14)(q11;q32)* chromosome translocation. Accordingly, *TCL-1* gene sequences may be used diagnostically for the detection of disease states resulting from chromosomal abnormalities, e.g., translocations, inversions and deletions, involving the *TCL-1* locus of chromosome 14. Nucleic acids comprising *TCL-1* nucleotide sequences of at least 8 nucleotides, at least 15 nucleotides, at least 25 nucleotides, at least 50 nucleotides, at least 100 nucleotides, at least 200 nucleotides, at least 300 nucleotides, or at least 387 nucleotides up to 1324 nucleotides of SEQ ID NO: 1 may be used as probes in hybridization assays for the detection and measurement of *TCL-1* gene. Nucleic acids of not more than 5 kilobases, of not more than 10 kilobases, not more than 25 kilobases, not more than 50 kilobases or not more than 70 kilobases which are hybridizable to a *TCL-1* gene, cDNA, or complementary strand can be used as probes in hybridization assays for the detection and measurement of *TCL-1* nucleotide sequences. As an example, the *TCL-1* DNA sequence may be used in hybridization assays, e.g., Southern or Northern analysis, including *in situ* hybridization assays, of patient's samples to diagnose abnormalities of *TCL-1* expression. Hybridization assays can be used to detect, prognose, diagnose, or monitor conditions, disorders, or disease states, such as T-cell malignancies, associated with aberrant changes in *TCL-1* expression and/or activity as described *supra*. In particular, such a hybridization assay is carried out by a method comprising contacting a sample containing nucleic acid with a nucleic acid probe capable of hybridizing to *TCL-1* DNA or RNA, under conditions such that hybridization can occur, and

detecting or measuring any resulting hybridization. In particular, hybridization assays can be used to detect the presence of abnormalities associated with increased expression of TCL-1 mRNA, by hybridizing mRNA or cDNA from a patient sample to a TCL-1 probe, and measuring the amount of resulting hybridization. For example, assays which can be used include, but are not limited to Northern blots, Dot blots, reverse transcriptase PCR, etc. A preferred hybridization assay is Northern blot analysis of a patient sample using TCL-1 gene probes of at least 15 polynucleotides up to the full length cDNA sequence shown in Figure 3A. Another preferred hybridization assay is *in situ* hybridization analysis of a patient sample using anti-TCL-1 antibodies or TCL-1 nucleotide hybridization probes. Such techniques are well known in the art, and are in fact the basis of many commercially available diagnostic kits.

As used herein, patient samples which can be used include, but are not limited to, fresh or frozen tissue samples, which can be used in *in situ* hybridization assays; cell or tissue samples containing T-lymphocytes and, in general, patient samples containing nucleic acid, such as peripheral blood lymphocytes (PBL) and T-lymphocytes which can be used in assays that measure or quantitate TCL-1 nucleic acid.

Polynucleotide sequences of TCL-1 consisting of at least 8 to 25 nucleotides that are useful as primers in primer dependent nucleic acid amplification methods may be used for the detection of TCL-1 gene sequences in patient samples. Primer dependent nucleic acid amplification methods useful in the present invention include, but are not limited to, polymerase chain reaction (PCR), competitive PCR, cyclic probe reaction, and ligase chain reaction. Such techniques are well known by those of skill in the art. A preferred nucleic acid amplification method of the present invention is reverse transcriptase PCR (RT-PCR) Siebert et al., 1992, Nature 359:557-558).

In a particular embodiment of the present invention, each primer of a pair of primers for use in a primer dependent nucleic acid amplification method is selected from a different exon of the genomic *TCL-1* nucleotide sequences. For example, 5 if one primer of a pair or primers is selected from exon 1 of the *TCL-1* genomic sequence, the second primer will be selected from exon 2, 3 or 4 of the *TCL-1* genomic sequence. As another example, if one primer of a pair of primers is selected from exon 2 of the *TCL-1* genomic sequence, the second primer will 10 be selected from exon 1, 3, or 4 of the *TCL-1* genomic sequence. By selecting each primer of a pair of primers for use in a primer dependent nucleic acid amplification method from a different exon, amplified genomic nucleotide sequences can be distinguished from amplified cDNA nucleotide sequences 15 due to the size difference of the resulting amplified sequences. Resulting amplified genomic nucleotide sequences will contain amplified intron sequences and will be of a larger size than amplified cDNA nucleotide sequences that will not contain amplified intron sequences. For amplification of 20 cDNA nucleotide sequences, the primer sequences should be selected from exons sequences that are sufficiently far enough apart to provide a detectable amplified nucleotide sequence.

The *TCL-1* gene sequences of the present invention may be used diagnostically for the detection of chromosome 14 25 abnormalities, in particular translocations  $t(14:14)(q11;q32)$  and  $inv(14)(q11;q32)$  inversion at 14q32.1. Accordingly, the present invention provides a process for detecting a target sequence indicative of or including a chromosome 14 abnormality in a sample, comprising the steps of amplifying 30 the target sequence in the sample using a first primer of 8 to 25 nucleotides, preferably 18-25 nucleotides, complementary to the nucleotide sequence of SEQ ID NO: 1 or SEQ ID NO: 3, and a second primer complementary to a region teleomeric or centromeric to the *TCL-1* gene and detecting any resulting 35 amplified target sequence in which the presence of the amplified target sequence is indicative of the abnormality. The present invention also provides a method of diagnosing a

T-cell malignancy associated with chromosome 14 abnormalities in a patient comprising, detecting said chromosome 14 abnormality according to the method above in which the presence of the amplified target sequence indicates the presence of a T-cell malignancy in the patient. The resultant amplified target sequence can be detected on gel electrophoresis and compared with a normal sample or standard that does not contain a chromosome 14 abnormality. Virgilio et al., supra, disclose polynucleotide sequences useful as second primers. Other polynucleotide sequences useful as second primers can be selected from the T-cell receptor  $\alpha/\delta$  locus, the T-cell receptor  $\beta$  chain, or if the chromosome 14 abnormality involves an inversion, a polynucleotide sequence 5' to exon 1 of the TCL-1 gene, or if the chromosome abnormality involves a translocation, a polynucleotide sequence 3' to the 3' intron of the TCL-1 gene. The amplification of genomic DNA target sequences may require generating long PCR products. PCR techniques for generating long PCR products are described in Science (1994) 263:1564-1565; PCR kits for generating long PCR products are available from Perkin Elmer and Takara Shuzo Co., Ltd. The present invention also provides a method for detecting a target nucleotide sequence indicative of or including at least a portion of a chromosome 14 abnormality in a nucleic acid sample, comprising the steps of hybridizing the sample with a nucleic acid probe of not more than 10 kilobases, comprising in the range of 15-1324 nucleotides complementary to at least a portion of the nucleotide sequence of SEQ ID NO: 1; and detecting or measuring the amount of any resulting hybridization between the probe and the target sequence within the sample. The resultant hybridization between the probe and the target sequence within the sample can be detected using gel electrophoresis and can be compared to a target sequence from a normal sample or standard that does not contain a chromosome 14 abnormality. The present invention also provides a method of diagnosing a T-cell malignancy associated with chromosome 14 abnormalities in a patient comprising,

detecting said chromosome 14 abnormality according to the method above in which the presence of the amplified target sequence indicates the presence of a T-cell malignancy in the patient. Absolute complementarity between a hybridization probe and a target sequence, although preferred, is not required. A sequence "complementary to at least a portion of", as referred to herein, means a sequence having sufficient complementarity to be able to hybridize with the nucleic acid, forming a stable hybridization complex. The ability to hybridize will depend on both the degree of complementarity and the length of the nucleic acid. Generally, the longer the hybridizing nucleic acid, the more base mismatches with a *TCL-1* RNA it may contain and still form a stable duplex (or triplex, as the case may be). One skilled in the art can ascertain a tolerable degree of mismatch by use of standard procedures to determine the melting point of the hybridized complex.

An additional aspect of the present invention relates to diagnostic kits for the detection or measurement of *TCL-1* gene sequences and *TCL-1* protein. Accordingly, the present invention provides a diagnostic kit comprising, in a container a compound comprising a probe of not more than 10 kilobases and comprising in the range of 15-1324 nucleotides of the nucleotide sequence of SEQ ID NO: 1 or its complement. Alternatively, the present invention provides a diagnostic kit comprising, in one or more containers, a pair of primers of at least 8-25 nucleotides in which at least one of said primers is hybridizable to SEQ ID NO: 1 or its complement and wherein said primers are capable of priming cDNA synthesis in an amplification reaction. The present invention also provides a diagnostic kit in which at least one of the primers is hybridizable to SEQ ID NO: 1 or its complement and in which one of the primers is hybridizable to a DNA sequence located telomeric or centromeric to the *TCL-1* gene. In a specific embodiment, one of the foregoing compounds of the container can be detectably labeled.

The amplification reaction of the present invention may be a polymerase chain reaction, competitive PCR and competitive reverse-transcriptase PCR (Clementi et al., 1994, Genet Anal Tech Appl 11(1):1-6 and Siebert et al., 1992, Nature 359:557-558); cyclic probe reaction, which allows for amplification of a target sequence using a hybrid RNA/DNA probe and RNase (ID Biomedical); ligase chain reaction (Wu et al. (1989) Genomics vol. 4, pp. 560-569). In a particular embodiment, the chromosomal abnormality associated with a TCL-1 locus can be detected as described in PCT Publication No. WO/92/19775, dated November 12, 1992. In a specific embodiment, the TCL-1 probe used in a hybridization assay is detectably labeled. Such a label can be any known in the art including, but not limited to, radioactive labels, fluorescent labels, biotin, chemiluminescent labels, etc.

In a specific embodiment in which the assay used employs primers, at least one primer can be detectably labeled. In another embodiment, one of a primer pair is attached to a moiety providing for capture, e.g., a magnetic bead.

Anti-TCL-1 antibodies may be generated and used diagnostically to detect the presence of TCL-1 protein product in patient samples thereby identifying disease states associated with chromosome 14 abnormalities. For detection of TCL-1 protein sequences, a diagnostic kit of the present invention comprises, in one or more containers, an anti-TCL-1 antibody which optionally can be detectably labeled. In a different embodiment, the kit can comprise in a container, a labeled specific binding portion of an antibody. As used herein, the term detectable label refers to any label which provides directly or indirectly a detectable signal and includes, for example, enzymes, radiolabelled molecules, fluorescent molecules, particles, chemiluminesors, enzyme substrates or cofactors, enzyme inhibitors, or magnetic particles. Examples of enzymes useful as detectable labels in the present invention include alkaline phosphatase and horse radish peroxidase. A variety of methods are available for linking the detectable labels to proteins of interest and

include for example the use of a bifunctional agent, such as, 4,4'-difluoro-3,3'-dinitro-phenylsulfone, for attaching an enzyme, for example, horse radish peroxidase, to a protein of interest. The attached enzyme is then allowed to react with a substrate yielding a reaction product which is detectable. The present invention provides a method for detecting a TCL-1 protein in a patient sample, comprising, contacting the patient sample with an anti-TCL-1 antibody under conditions such that immunospecific binding can occur, and detecting or measuring the amount of any immunospecific binding by the antibody.

Samples can be any sample from a patient containing TCL-1 protein, e.g., tissue sections, peripheral blood lymphocytes, etc.

In diagnosing disease states, the functional activity of TCL-1 proteins, derivatives and analogs may be assayed by various methods. Accordingly, the present invention also provides a method of diagnosing a T-cell malignancy associated with chromosome 14 abnormalities in a patient comprising, detecting increased expression of TCL-1 protein in a sample from the patient, in which an increase in TCL-1 protein relative to the level found in such an analogous sample from a normal individual, indicates the presence of a T-cell malignancy in the patient.

For example, in one embodiment, where one is detecting or measuring TCL-1 protein by assaying for binding to anti-TCL-1 antibody, various immunoassays known in the art can be used, including but not limited to competitive and non-competitive assay systems using techniques such as radioimmunoassays, ELISA (enzyme linked immunosorbent assay), "sandwich" immunoassays, immunoradiometric assays, gel diffusion precipitin reactions, immunodiffusion assays, in situ immunoassays (using colloidal gold, enzyme or radioisotope labels, for example), western blots, in situ hybridizations, precipitation reactions, agglutination assays (e.g., gel agglutination assays, hemagglutination assays), complement fixation assays, immunofluorescence assays, protein A assays,

and immunoelectrophoresis assays, etc. In one embodiment, antibody binding is detected by detecting a label on the primary antibody. In another embodiment, the primary antibody is detected by detecting binding of a secondary antibody or reagent to the primary antibody. In a further embodiment, the secondary antibody is labelled. Many means are known in the art for detecting binding in an immunoassay and are within the scope of the present invention. In particular, such an immunoassay is carried out by a method comprising contacting a sample derived from a patient with an anti-TCL-1 antibody under conditions such that immunospecific binding can occur, and detecting or measuring the amount of any immunospecific binding by the antibody. In a specific embodiment, antibody to a TCL-1 protein can be used to assay a patient tissue or serum sample for the presence of a TCL-1 protein where an increased level of TCL-1 protein is an indication of a diseased condition. In one embodiment of the present invention, the TCL-1 protein is detected or measured by immunocytochemistry of a patient sample. In another embodiment, assays to measure the levels of TCL-1 protein or RNA can be used to monitor therapy of disease associated with increased expression of TCL-1. For example, a decrease in levels of TCL-1 RNA or protein after therapy, relative to the level found before therapy, may be indicative of a favorable response to therapy. An increase in such levels after therapy may be indicative of a poor response to therapy.

In another embodiment, the levels of TCL-1 protein or RNA expression may be used to stage disease, with an increase in TCL-1 protein or RNA expression indicating disease progression.

Other methods will be known to the skilled artisan and are within the scope of the invention.

#### 5.8.2. Therapeutic/Prophylactic Uses

Inhibitors of TCL-1 may be used therapeutically for the treatment of disease states associated with chromosome 14 abnormalities, in particular at 14q32.1, and/or increased

expression of TCL-1 protein. In an embodiment of the present invention, a TCL-1 protein and/or cell line that expresses a TCL-1 protein can be used to screen for antibodies, peptides, or other molecules that bind to the TCL-1 protein and thus may  
5 act as agonists or antagonists of TCL-1 protein. For example, anti-TCL-1 antibodies capable of neutralizing the activity of a TCL-1 protein may be used to inhibit or prevent a disease state associated with chromosome 14 abnormalities and/or expression of TCL-1 protein, such as T-cell leukemia and  
10 lymphoma. Accordingly, the present invention provides a method for treating a disease state associated with a chromosome 14 abnormality in mammal suffering from a disease state associated with a chromosome 14 abnormality comprising, administering a therapeutically effective amount of an anti-  
15 TCL-1 antibody to a mammal suffering from a disease state associated with a chromosome 14 abnormality. Alternatively, screening of organic or peptide libraries with recombinantly expressed TCL-1 protein may be useful for identification of therapeutic molecules that function to inhibit the activity of  
20 TCL-1 protein. Synthetic and naturally occurring products can be screened in a number of ways deemed routine to those of skill in the art.

The ability of antibodies, peptides or other molecules to modulate the effect of TCL-1 protein on disease states may be  
25 monitored. For example, the expression of *TCL-1* gene sequences or TCL-1 protein sequences may be detected as described, *supra*, both before and after administration of a therapeutic composition comprising a *TCL-1* nucleotide sequence, TCL-1 protein sequence, derivative or analog  
30 thereof, or antibody thereto, of the present invention.

A *TCL-1* polynucleotide may be useful in the treatment of various disease states associated with chromosome 14 abnormalities, such as T-cell leukemias and lymphomas, and/or increased expression of TCL-1 protein. By introducing *TCL-1*  
35 antisense gene sequences into cells, gene therapy can be used to treat conditions associated with over-expression of *TCL-1* genes. Accordingly, the present invention provides a method

for treating a disease state associated with a chromosome 14 abnormality in mammal suffering from a disease state associated with a chromosome 14 abnormality comprising, administering a therapeutically effective amount of a *TCL-1* antisense molecule to a mammal suffering from a disease state associated with a chromosome 14 abnormality.

Oligonucleotide sequences, that include antisense RNA and DNA molecules and ribozymes that function to inhibit the translation of a *TCL-1* mRNA are within the scope of the invention. "Antisense" as used herein refers to a nucleic acid capable of hybridizing to a portion of a *TCL-1* RNA (preferably mRNA) by virtue of some sequence complementarity. Antisense RNA and DNA molecules act to directly block the translation of mRNA by binding to targeted mRNA and preventing protein translation. In regard to antisense DNA, oligodeoxyribonucleotides derived from the translation initiation site, e.g., between -10 and +10 regions of a *TCL-1* nucleotide sequence, are preferred. The present invention provides for an antisense molecule comprising a nucleotide sequence complementary to at least a part of the coding sequence of a *TCL-1* protein which is hybridizable to a *TCL-1* mRNA. The present invention also provides for an antisense molecule comprising a nucleotide sequence complementary to at least a part of the non-coding sequence depicted in Figure 3B (SEQ ID NO: 3) or Figure 9 (SEQ ID NO: 5) which hybridizes to said sequence depicted in Figure 3B (SEQ ID NO: 3) or Figure 9 (SEQ ID NO: 5), respectively. In a preferred embodiment of the present invention, the antisense gene sequence is derived from the 5' non-coding sequence of a *TCL-1* gene. In a particularly preferred embodiment of the present invention, the antisense gene sequence is derived from SEQ ID NO: 3.

Ribozymes are enzymatic RNA molecules capable of catalyzing the specific cleavage of RNA. The mechanism of ribozyme action involves sequence specific hybridization of the ribozyme molecule to complementary target RNA, followed by an endonucleolytic cleavage. Within the scope of the invention are engineered hammerhead motif ribozyme molecules that

specifically and efficiently catalyze endonucleolytic cleavage of TCL-1 RNA sequences.

Specific ribozyme cleavage sites within any potential RNA target are initially identified by scanning the target molecule for ribozyme cleavage sites which include the following sequences, GUA, GUU and GUC. Once identified, short RNA sequences of between 15 and 20 ribonucleotides corresponding to the region of the target gene containing the cleavage site may be evaluated for predicted structural features such as secondary structure that may render the oligonucleotide sequence unsuitable. The suitability of candidate targets may also be evaluated by testing their accessibility to hybridization with complementary oligonucleotides, using ribonuclease protection assays.

Both anti-sense RNA and DNA molecules and ribozymes of the invention may be prepared by any method known in the art for the synthesis of RNA molecules. These include techniques for chemically synthesizing oligodeoxyribonucleotides well known in the art such as for example solid phase phosphoramidite chemical synthesis. Alternatively, RNA molecules may be generated by *in vitro* and *in vivo* transcription of DNA sequences encoding the antisense RNA molecule. Such DNA sequences may be incorporated into a wide variety of vectors which incorporate suitable RNA polymerase promoters such as the T7 or SP6 polymerase promoters. Alternatively, antisense cDNA constructs that synthesize antisense RNA constitutively or inducibly, depending on the promoter used, can be introduced stably into cell lines.

Various modifications to the DNA molecules may be introduced as a means of increasing intracellular stability and half-life. Possible modifications include but are not limited to the addition of flanking sequences of ribo- or deoxy- nucleotides to the 5' and/or 3' ends of the molecule or the use of phosphorothioate or 2' O-methyl rather than phosphodiesterase linkages within the oligodeoxyribonucleotide backbone.

Methods for introducing nucleic acid into cells or tissue include methods for *in vitro* introduction of nucleic acid such as the insertion of naked nucleic acid, i.e., by injection into tissue, the introduction of a nucleic acid in a cell *ex vivo*, the use of a vector such as a virus, retrovirus, phage or plasmic, etc. or techniques such as electroporation which may be used *in vivo* or *ex vivo*.

Other methods will be known to the skilled artisan and are within the scope of the invention.

10

### 5.9. Demonstration of Therapeutic or Prophylactic Utility

The TCL-1 polynucleotides, TCL-1 protein products, derivatives and analogs thereof, and antibodies thereto, of the invention can be tested *in vivo* for the desired therapeutic or prophylactic activity. For example, such compounds can be tested in suitable animal model systems prior to testing in humans, including but not limited to rats, mice, chicken, cows, monkeys, rabbits, etc. For *in vivo* testing, prior to administration to humans, any animal model system known in the art may be used.

20

#### 5.9.1. Therapeutic/Prophylactic Methods and Compositions

The invention provides methods of treatment and prophylaxis by administration to a subject of an effective amount of a Therapeutic, i.e., a TCL-1 polynucleotide, TCL-1 protein, derivative or analog thereof, or antibody thereto of the present invention. In a preferred aspect, the Therapeutic is substantially purified. The subject is preferably an animal, including but not limited to animals such as cows, pigs, chickens, etc., and is preferably a mammal, and most preferably human.

30

Various delivery systems are known and can be used to administer a Therapeutic of the invention, e.g., encapsulation in liposomes, microparticles, microcapsules, expression by recombinant cells, receptor-mediated endocytosis (see, e.g.,

35

Wu and Wu, 1987, J. Biol. Chem. 262:4429-4432), construction of a therapeutic nucleic acid as part of a retroviral or other vector, etc. Methods of introduction include but are not limited to intradermal, intramuscular, intraperitoneal, 5 intravenous, subcutaneous, intranasal, and oral routes. The compounds may be administered by any convenient route, for example by infusion or bolus injection, by absorption through epithelial or mucocutaneous linings (e.g., oral mucosa, rectal and intestinal mucosa, etc.) and may be administered together 10 with other biologically active agents. Administration can be systemic or local. In addition, it may be desirable to introduce the pharmaceutical compositions of the invention into the central nervous system by any suitable route, including intraventricular and intrathecal injection; 15 intraventricular injection may be facilitated by an intraventricular catheter, for example, attached to a reservoir, such as an Ommaya reservoir.

In a specific embodiment, it may be desirable to administer the pharmaceutical compositions of the invention 20 locally to the area in need of treatment; this may be achieved by, for example, and not by way of limitation, local infusion during surgery, topical application, e.g., in conjunction with a wound dressing after surgery, by injection, by means of a catheter, by means of a suppository, or by means of an 25 implant, said implant being of a porous, non-porous, or gelatinous material, including membranes, such as sialastic membranes, or fibers. In one embodiment, administration can be by direct injection at the site (or former site) of a malignant tumor or neoplastic or pre-neoplastic tissue.

30 In a specific embodiment where the Therapeutic is a nucleic acid encoding a protein therapeutic, the nucleic acid can be administered *in vivo* to promote expression of its encoded protein, by constructing it as part of an appropriate nucleic acid expression vector and administering it so that it 35 becomes intracellular, e.g., by use of a retroviral vector (see U.S. Patent No. 4,980,286), or by direct injection, or by use of microparticle bombardment (e.g., a gene gun; Biolistic,

Dupont), or coating with lipids or cell-surface receptors or transfecting agents, or by administering it in linkage to a homeobox-like peptide which is known to enter the nucleus (see e.g., Joliot et al., 1991, Proc. Natl. Acad. Sci. USA 5 88:1864-1868), etc. Alternatively, a nucleic acid therapeutic can be introduced intracellularly and incorporated within host cell DNA for expression, by homologous recombination.

The present invention also provides pharmaceutical compositions. Such compositions comprise a therapeutically 10 effective amount of a therapeutic, and a pharmaceutically acceptable carrier or excipient. Such a carrier includes but is not limited to saline, buffered saline, dextrose, water, glycerol, ethanol, and combinations thereof. The carrier and composition can be sterile. The formulation should suit the 15 mode of administration.

The composition, if desired, can also contain minor amounts of wetting or emulsifying agents, or pH buffering agents. The composition can be a liquid solution, suspension, emulsion, tablet, pill, capsule, sustained release 20 formulation, or powder. The composition can be formulated as a suppository, with traditional binders and carriers such as triglycerides. Oral formulation can include standard carriers such as pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium 25 carbonate, etc.

In a preferred embodiment, the composition is formulated in accordance with routine procedures as a pharmaceutical composition adapted for intravenous administration to human beings. Typically, compositions for intravenous 30 administration are solutions in sterile isotonic aqueous buffer. Where necessary, the composition may also include a solubilizing agent and a local anesthetic such as lignocaine to ease pain at the site of the injection. Generally, the ingredients are supplied either separately or mixed together 35 in unit dosage form, for example, as a dry lyophilized powder or water free concentrate in a hermetically sealed container such as an ampoule or sachette indicating the quantity of

active agent. Where the composition is to be administered by infusion, it can be dispensed with an infusion bottle containing sterile pharmaceutical grade water or saline. Where the composition is administered by injection, an ampoule  
5 of sterile water for injection or saline can be provided so that the ingredients may be mixed prior to administration.

The Therapeutics of the invention can be formulated as neutral or salt forms. Pharmaceutically acceptable salts include those formed with free amino groups such as those  
10 derived from hydrochloric, phosphoric, acetic, oxalic, tartaric acids, etc., and those formed with free carboxyl groups such as those derived from sodium, potassium, ammonium, calcium, ferric hydroxides, isopropylamine, triethylamine, 2-ethylamino ethanol, histidine, procaine, etc.

15 The amount of the Therapeutic of the invention which will be effective in the treatment of a particular disorder or condition will depend on the nature of the disorder or condition, and can be determined by standard clinical techniques. In addition, *in vitro* assays may optionally be  
20 employed to help identify optimal dosage ranges. The precise dose to be employed in the formulation will also depend on the route of administration, and the seriousness of the disease or disorder, and should be decided according to the judgment of the practitioner and each patient's circumstances. However,  
25 suitable dosage ranges for intravenous administration are generally about 20-500 micrograms of active compound per kilogram body weight. Suitable dosage ranges for intranasal administration are generally about 0.01 pg/kg body weight to 1 mg/kg body weight. Effective doses may be extrapolated from  
30 dose-response curves derived from *in vitro* or animal model test systems.

Suppositories generally contain active ingredient in the range of 0.5% to 10% by weight; oral formulations preferably contain 10% to 95% active ingredient.

35 The invention also provides a pharmaceutical pack or kit comprising one or more containers filled with one or more of the ingredients of the pharmaceutical compositions of the

invention. Optionally associated with such container(s) can be a notice in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects approval by the agency of manufacture, use or sale for human administration.

#### 5.9.2. Antisense Regulation of TCL-1 Gene Expression

The present invention provides the therapeutic or prophylactic use of nucleic acids of at least six nucleotides that are antisense to a gene or cDNA encoding TCL-1 or a portion thereof (see also Section 5.8.2). Such antisense nucleic acids have utility as Antagonist Therapeutics of the invention, and can be used in the treatment or prevention of disorders, e.g., T-cell malignancies as described supra in Section 5.8.

The antisense nucleic acids of the invention can be oligonucleotides that are double-stranded or single-stranded, RNA or DNA or a modification or derivative thereof, which can be directly administered to a cell, or which can be produced intracellularly by transcription of exogenous, introduced sequences.

In a specific embodiment, the TCL-1 antisense polynucleotides provided by the instant invention can be used for the treatment of disease states associated with chromosome 14 abnormalities, in particular at 14q32.1, wherein the disease state can be demonstrated (*in vitro* or *in vivo*) to express the TCL-1 gene. Such demonstration can be by detection of TCL-1 RNA or of TCL-1 protein.

The invention further provides pharmaceutical compositions comprising an effective amount of the TCL-1 antisense nucleic acids of the invention in a pharmaceutically acceptable carrier, as described supra in Section 5.9.1. Methods for treatment and prevention of disease states associated with chromosome 14, such as T-cell malignancies comprising administering the pharmaceutical compositions of the invention are also provided.

In another embodiment, the invention is directed to methods for inhibiting the expression of a *TCL-1* nucleic acid sequence in a prokaryotic or eukaryotic cell comprising providing the cell with an effective amount of a composition  
5 comprising an antisense *TCL-1* nucleic acid of the invention.

The *TCL-1* antisense polynucleotides are of at least six nucleotides and are preferably oligonucleotides (ranging from 6 to about 50 oligonucleotides). In specific aspects, the oligonucleotide is at least 10 nucleotides, at least 20  
10 nucleotides, at least 30 nucleotides, or at least 40 nucleotides. The oligonucleotides can be DNA or RNA or chimeric mixtures or derivatives or modified versions thereof, single-stranded or double-stranded. The oligonucleotide can be modified at the base moiety, sugar moiety, or phosphate  
15 backbone. The oligonucleotide may include other appending groups such as peptides, or agents facilitating transport across the cell membrane (see, e.g., Letsinger et al., 1989, Proc. Natl. Acad. Sci. USA 86:6553-6556; Lemaitre et al., 1987, Proc. Natl. Acad. Sci. USA 84:648-652; PCT Publication  
20 No. WO 88/09810, published December 15, 1988) or blood-brain barrier (see, e.g., PCT Publication No. WO 89/10134, published April 25, 1988), hybridization-triggered cleavage agents (see, e.g., Krol et al., 1988, BioTechniques 6:958-976) or intercalating agents (see, e.g., Zon, 1988, Pharm. Res. 5:539-  
25 549).

The oligonucleotide may be conjugated to another molecule, e.g., a peptide, hybridization triggered cross-linking agent, transport agent, hybridization-triggered cleavage agent, etc.

30 Oligonucleotides of the invention may be synthesized by standard methods known in the art, e.g., by use of an automated DNA synthesizer (such as are commercially available from Biosearch, Applied Biosystems, etc.). As examples, phosphorothioate oligos may be synthesized by the method of  
35 Stein et al. (1988, Nucl. Acids Res. 16:3209), methylphosphonate oligos can be prepared by use of controlled

pore glass polymer supports (Sarin et al., 1988, Proc. Natl. Acad. Sci. USA. 85:7448-7451), etc.

In a specific embodiment, the TCL-1 antisense oligonucleotide comprises catalytic RNA, or a ribozyme (see, 5 e.g., PCT International Publication WO 90/11364, published October 4, 1990; Sarver et al., 1990, Science 247:1222-1225). In another embodiment, the oligonucleotide is a 2'-O-methylribonucleotide (Inoue et al., 1987, Nucl. Acids Res. 15:6131-6148), or a chimeric RNA-DNA analogue (Inoue et al., 10 1987, FEBS Lett. 215:327-330).

In an alternative embodiment, the TCL-1 antisense nucleic acid of the invention is produced intracellularly by transcription from an exogenous sequence. For example, a vector can be introduced in vivo such that it is taken up by a 15 cell, within which cell the vector or a portion thereof is transcribed, producing an antisense nucleic acid (RNA) of the invention. Such a vector would contain a sequence encoding the TCL-1 antisense nucleic acid. Such a vector can remain episomal or become chromosomally integrated, as long as it can 20 be transcribed to produce the desired antisense RNA. Such vectors can be constructed by recombinant DNA technology methods standard in the art. Vectors can be plasmid, viral, or others known in the art, used for replication and expression in mammalian cells. Expression of the sequence 25 encoding the TCL-1 antisense RNA can be by any promoter known in the art to act in mammalian, preferably human, cells. Such promoters can be inducible or constitutive. Such promoters include but are not limited to: the SV40 early promoter region (Bernoist and Chambon, 1981, Nature 290:304-310), the promoter 30 contained in the 3' long terminal repeat of Rous sarcoma virus (Yamamoto et al., 1980, Cell 22:787-797), the herpes thymidine kinase promoter (Wagner et al., 1981, Proc. Natl. Acad. Sci. USA 78:1441-1445), the regulatory sequences of the metallothionein gene (Brinster et al., 1982, Nature 296:39- 35 42), etc.

The antisense nucleic acids of the invention comprise a sequence complementary to at least a portion of an RNA

transcript of a *TCL-1* gene, preferably a human *TCL-1* gene. However, absolute complementarity, although preferred, is not required. A sequence "complementary to at least a portion of an RNA," as referred to herein, means a sequence having  
5 sufficient complementarity to be able to hybridize with the RNA, forming a stable duplex; in the case of double-stranded *TCL-1* antisense nucleic acids, a single strand of the duplex DNA may thus be tested, or triplex formation may be assayed. The ability to hybridize will depend on both the degree of  
10 complementarity and the length of the antisense nucleic acid. Generally, the longer the hybridizing nucleic acid, the more base mismatches with a *TCL-1* RNA it may contain and still form a stable duplex (or triplex, as the case may be). One skilled in the art can ascertain a tolerable degree of mismatch by use  
15 of standard procedures to determine the melting point of the hybridized complex.

The *TCL-1* antisense nucleic acids can be used to treat (or prevent) T-cell malignancies, of a cell type which has been shown to express *TCL-1* RNA. Malignant, neoplastic, and  
20 pre-neoplastic cells which can be tested for such expression include but are not limited to those described *supra* in Sections 5.8. In a preferred embodiment, a single-stranded DNA antisense *TCL-1* oligonucleotide is used.

Malignant (particularly, tumor) cell types which express  
25 *TCL-1* RNA can be identified by various methods known in the art. Such methods include but are not limited to hybridization with a *TCL-1*-specific nucleic acid (e.g., by Northern hybridization, dot blot hybridization, *in situ* hybridization), observing the ability of RNA from the cell  
30 type to be translated *in vitro* into *TCL-1*, etc. In a preferred aspect, primary tumor tissue from a patient can be assayed for *TCL-1* expression prior to treatment.

Pharmaceutical compositions of the invention, comprising an effective amount of a *TCL-1* antisense nucleic acid in a  
35 pharmaceutically acceptable carrier, can be administered to a patient having a malignancy which is of a type that expresses *TCL-1* RNA.

The amount of TCL-1 antisense nucleic acid which will be effective in the treatment of a particular disease state or condition will depend on the nature of the disease state or condition, and can be determined by standard clinical techniques. Where possible, it is desirable to determine the antisense cytotoxicity of the tumor type to be treated in vitro, and then in useful animal model systems prior to testing and use in humans.

In a specific embodiment, pharmaceutical compositions comprising TCL-1 antisense nucleic acids are administered via liposomes, microparticles, or microcapsules. In various embodiments of the invention, it may be useful to use such compositions to achieve sustained release of the TCL-1 antisense nucleic acids. In a specific embodiment, it may be desirable to utilize liposomes targeted via antibodies to specific identifiable tumor antigens (Leonetti et al., 1990, Proc. Natl. Acad. Sci. USA 87:2448-2451; Renneisen et al., 1990, J. Biol. Chem. 265:16337-16342).

## 6. IDENTIFICATION OF THE TCL-1 GENE

This example describes the isolation and characterization of the TCL-1 gene. Two procedures were undertaken in order to isolate the TCL-1 gene. In one procedure, cDNA libraries, constructed from mRNA from an endemic Burkitt lymphoma cell line and two pre-B cell lines, Daudi, 697 and ALL1 were screened using unique probes from the TCL-1 locus on chromosome 14. In the second procedure, exon trapping method (Nehls et al., 1994, Oncogene 9(8):2169-2175; Verna et al., 1993, Nucleic Acids Res. 21(22):5198:5202; and Auch et al., 1990, Nucleic Acids Res. 18(22):6743-6744) using genomic DNA from P1 clones 7-4 and 20-21 was performed.

### 6.1. Materials and Methods

#### 6.1.1. Isolation of Unique Probes

Unique probes for the isolation of TCL-1 were derived from the human genomic library P1 prepared from human placental DNA (Virgilio et al., 1993, Proc. Natl. Acad. Sci.

USA 90:9275-9279)). Virgilio et al., identified P1 library clones 7-4 and 20-21 which were doubly digested, the former with *ClaI* and *EcoRI*, and the latter with *SalI* and *EcoRI* or with *EagI* and *HindIII*, and then subcloned in the vector pBS II 5 available from Stratagene. The subclones were cultured, their DNA was prepared by standard miniprep preparation method and positive subclones were identified (Sambrook et al., 1989, Molecular Cloning, A Laboratory Manual, 2d ed., Cold Spring Harbor Lab. Press, New York). Repeat free DNA fragments were 10 identified by Southern blot hybridization with human cot-1 DNA (Sambrook et al., 1989, Molecular Cloning, A Laboratory Manual, 2d ed., Cold Spring Harbor Lab. Press, New York).

#### 6.1.2. Exon Trapping

15 The pE53 vector, a reproduction of the pMHC2 vector (Hamaguchi et al., 1992, Proc. Natl. Acad. Sci. USA 89:9779-9783), was provided by Dr. M. Ohta, at the Jefferson Cancer Institute. It contains a portion of p53 exon 10, intron 10, and a portion of exon 11. A unique *BglII* site is present in 20 intron 10 for cloning. One mg of the DNA of P1 clones 7-4 and 20-21 was partially digested with *Sau3A* and the digested DNA of molecular weight between 0.5 Kb and 5Kb was isolated and cloned into the *BglII* site of pE53. 5 to 10 mg was transfected into semi-confluent COS-7 cells using lipofectase 25 (available from BRL). After 30 hours, total RNA was isolated as described by Buckler et. al. (1991, Proc. Natl. Acad. Sci. USA 88:4005-4009). Amplification of total RNA by reverse transcription-PCR was carried out with primers and procedures described by Hamaguchi et. al. (1992, Proc. Natl. Acad. Sci. 30 USA 89:9779-9783).

#### 6.1.3. Preparation of cDNA Libraries

A cDNA library from Daudi cell line was constructed with a commercial kit for 1 Zap cDNA synthesis, from Stratagene. 35 The ligation was packaged with Gigapak II Gold packaging extract (Stratagene). cDNA libraries constructed from the cell lines ALL1 and 697 were kindly donated by Dr. T. Nakamura

and Dr. A. ar-Rushdi respectively (both at Jefferson Cancer Institute). The libraries were plated and screened using standard protocols (Sambrook et al., 1989, Molecular Cloning, A Laboratory Manual, 2d ed., Cold Spring Harbor Lab. Press, 5 New York).

#### 6.1.4. Prokaryotic Expression

The expression vector pQE30, available from Qiagen, containing the *E. coli* phage T5 promoter, two lac operator  
10 sequences and a six histidine affinity tag coding sequences was used for expression of the TCL-1 gene. p697 cDNA was digested with *NcoI* and *EcoRI*, and the 5' protruding ends were filled in with the Klenow polymerase (Sambrook et al., 1989, Molecular Cloning, A Laboratory Manual, 2d ed., Cold Spring  
15 Harbor Lab. Press, New York). The purified DNA fragment was ligated to pQE30 previously digested with *BamHI* and treated with Klenow polymerase to blunt the ends. Positives clones were selected and the presence of a continuous open reading  
20 expression of the cloned sequences and purification of the recombinant product was performed according to Qiagen recommendation. A total of 1.5 mg of recombinant product was purified from 400 ml of culture.

#### 25 6.1.5. In Vitro Translation

The plasmid pALL1 containing full length TCL-1 cDNA was linearized by digestion with *ClaI* and transcribed and translated in vitro using the TNT Coupled Reticulocyte Lysate system according to manufacturer protocol (Promega). The  
30 resulting products were subjected to SDS-PAGE followed by autoradiography.

### 6.2. Results

#### 6.2.1. Cloning of the TCL-1 Gene

35 The search for the TCL-1 gene was focused on the region included between the two sets of breakpoints of approximately 160 kb on the TCL-1 locus of chromosome 14 encompassed by the

P1 clones 7-4 and 20-21 (Virgilio et al., 1993, Proc. Natl. Acad. Sci. USA 90:9275-9279), as illustrated in Figure 1. In the effort to identify transcribed sequences, the areas surrounding restriction sites of rare cutter enzymes in these 5 two P1 clones were subcloned and unique probes were isolated. The recognition sites of rare cutter enzymes such as *MluI*, *NruI* and *NotI*, which are rich in CG content, may indicate the existence of a CpG island. Such CpG islands are often found in the proximity of transcribed genes (Lindsay and Bird, 1987, 10 Nature 327:336-338). Four probes were generated in this way, 7-4CE, 20-7SE, 20-7HE and 9-1KK, whose position is shown in Figure 1, and hybridized to Northern blots containing RNAs from lymphoid and myelogenous cell lines. Only the probe 20-7HE and 20-7SE, derived from sequences adjacent to a *NotI* site 15 (Figure 1), hybridized with an mRNA from hematopoietic cell lines. This transcript of approximately 1.3kb in size, was clearly visible in the pre-B acute lymphoblastic leukemia (ALL) cell line ALL380 and in the endemic Burkitt lymphoma cell line Daudi (Figure 2). Three independent cDNA libraries, 20 constructed from RNA from an endemic Burkitt lymphoma cell line and two pre-B cell lines, Daudi, 697 and ALL1, all of which expressed high levels of the 1.3 kb transcript, were screened with the 20-7HE probe and positive clones were obtained from each library. These clones were designated 25 pA1Daudi, pA11.5 and p697.

In a parallel effort to identify transcripts, the P1 clones 20-21 and 7-4 were partially digested with *Sau3A* and cloned into an exon trapping vector containing exon 10, intron 10, and exon 11 of the *p53* gene. Several putative exons were 30 isolated, but the majority were due to aberrant splicing at cryptic splicing sites. Some trapped DNA fragments contained *Alu* repeat sequences and one had high homology to transposon like sequences. However, the sequence of one of the trapped fragments matched the sequence of the cDNA isolated from the 35 697 and ALL1 libraries and was later found to correspond to exon 3 of the gene.

### 6.2.2. Sequence Analysis of cDNA Clones

All three cDNA clones, pA1Daudi, pA11.5 and p697, were entirely sequenced and the complete sequence of pA11.5 is shown in Figure 3. Upon sequence comparison, pA11.5 and p697 cDNAs were found to be identical, except for a base pair substitution at position 404 where a C in pA11.5 is a T in p697 cDNA. pA1Daudi was incomplete at the 5' end, was missing the first 88 nucleotides, and additionally showed two small internal deletions, the pentamer ATGGT at position 394 and the octamer CTGCCCTT at position 707 (Figure 3). All three clones of cDNA had 3' untranslated regions of slightly different length. pA11.5 contained the longest one with the presence of a consensus polyadenylation signal at position 1293.

Sequence analysis of the isolated cDNAs showed the presence of two long open reading frames (ORF). Frame 1 contains an ORF of 342 nucleotides with a starting ATG codon at position 46, located within a perfect Kozak consensus sequence, and with a stop codon at position 388 (Figure 3). This ORF potentially encodes for a protein of 114 amino acids with a predicted molecular weight of 13.5 kDa. Frame 2 contains an ORF with a starting ATG codon at position 383 and a stop codon at position 773, to give a putative protein of 14.5 kDa in molecular weight. However the presence in this second ORF of a point mutation and a deletion in two of the three independently isolated cDNA clones, as well as the position of this ORF only on the last exon, led us to believe that the second ORF is not translated.

Search of nucleic acid and protein data bases, revealed about a 40% amino acid sequence homology between the TCL-1 protein and the Mature T-Cell Proliferative 1 protein (Stern et al.(1993) Oncogen, vol. 8 pp. 2475-2483) which is involved in a translocation of chromosome 14 and the X chromosome t(14:X)(q11;q28) also found to be associated with T-PLL and AT, see Figure 8. The GCG Motifs program revealed the existence of a casein kinase II phosphorylation site (MAECPTLGEAVTDH) (a portion of SEQ ID NO:2) starting at amino acid position 6. To confirm the presence of an open reading

frame and its ability to encode for a protein, the entire cDNA was subcloned into the prokaryotic expression vector pQE30. Figure 4 shows the specific induction of a 14kDa protein and the protein after purification. These results were also confirmed by *in vitro* translation. In order to study the genomic structure of the gene, a SalI-Hind III fragment, containing the entire cDNA, was subcloned and sequenced. The map and the structure of the gene are shown in Figure 1. The gene is composed by four small exons with a 3' untranslated region of approximately 800 nucleotides. The sequence immediately 5' to the cDNA showed the presence of five binding sites for the SP1 transcription factor and a TATA box at position -41 (Figure 3B); these data confirm that we have isolated a complete cDNA.

15

#### 6.2.3. Production of Polyclonal Anti-TCL-1 Antibodies

Recombinant TCL-1 protein, expressed in bacteria, was used to immunize rabbits. The antisera raised in the rabbits reacted with a protein of 14kDa expressed in bacteria containing the recombinant *TCL-1* gene, as shown by Western blot. The rabbit anti-TCL-1 antibodies were also able to immunoprecipitate a 14 kDa protein from a variety of leukemic and lymphoid cells expressing *TCL-1* mRNA.

25

### 7. EXPRESSION OF THE *TCL-1* GENE IN T-CELL MALIGNANCIES

This example illustrates the increased expression of the *TCL-1* gene in various T-cell malignancies.

30

#### 7.1. Materials and Methods

##### 7.1.1. Reverse transcription-PCR

Amplification of DNA from isolated populations of bone marrow B-cells, T-cell lines, PBL, PHA stimulated PBL and thymus was performed using reverse transcriptase PCR. First strand DNA synthesis was performed using 1 mg of total RNA with either M-MLV (available from BRL) or AMV or Superscript (available from BRL) reverse transcriptase and respective

35

reaction buffer with either oligo dT or random primers. One tenth of the reaction was subsequently used for each single PCR amplification. Amplification of DNA from isolated populations of bone marrow B-cells, T-cell lines, PBL, PHA stimulated PBL and thymus was carried out with TCL-1 primers p9A- TGCTGCCAGATGACTGATGT (SEQ ID NO: 6) and Rev III CAAATGGAATCCTCCTTGGC, (SEQ ID NO: 7) under the following conditions. The nucleic acid was denaturing for 1 min. at 94°C, then allowed to anneal for 1 min. at 58°C, then allowed to elongate for 1 min. at 72°C for a total of 30 cycles. Amplification of DNA from patients with T-PLL was carried out with TCL-1 primers Daudi unil- AGGCCTATGACCCCCACC (SEQ ID NO: 8) and Daudi rev2- CATTCCTCCCAGACCCCA, (SEQ ID NO: 9) under the same conditions as above, except for the annealing temperature which was 60°C. As PCR internal standard, primers specific for the B-actin gene were used: A1- TCATCACCATTGGCAATGAG (SEQ ID NO: 10) and A2- CAGTGTGTTGGCGTACAGGT (SEQ ID NO: 11). These primers were used under the same conditions as the TCL-1 primers.

20

#### 7.1.2. Isolation of Lymphocyte Cells by Immunofluorescence Cell-Sorting

Bone marrow cells were obtained from 18-22 week fetal material, in accordance with policies established by an institutional review board. Mononuclear bone marrow cells were then isolated by centrifugation of cell suspensions over a Ficoll-Hypaque gradient (Nishimoto et al., 1991, Proc. Natl. Acad. Sci. USA 88:6284-6288). The monoclonal antibodies (MAbs) used for cell surface analysis included anti-human Leu-12, which recognizes the pan-B cell antigen CD19, anti-human HPCA-2, which detects the early stem cell marker CD34 (Becton-Dickinson), and goat-anti-human IgM (Southern Biotechnology Associates). For two-color surface analysis for cell-sorting, viable FBM cells were incubated with fluorescein isothiocyanate (FITC)-conjugated anti CD34 antibodies or goat-anti-hu IgM for 15 minutes on ice, washed with PBS containing 2% HIFCS, and counterstained with phycoerythrin (PE)-

conjugated MAb specific for CD19. Subpopulations of lymphocytes were sorted according to immunofluorescence and light scatter characteristics with a FACS-Star instrument (Becton-Dickinson). The lymphocyte subpopulations collected 5 were CD34+CD19-, CD34+CD19+, CD19lom-, CD19hi m-, CD19+mlo, and CD19+mhi. Cells were collected, counted, and total RNA was extracted using Tri-Reagent (Molecular Research Center). RNA was subjected to Northern blot analysis to reveal the existence a TCL-1 transcript.

10

### 7.1.3. Cell Lines and Lymphocytes

A variety of human cell lines derived from T-cell leukemias were subjected to Northern blot analysis to detect the existence of a TCL-1 transcript. The majority of the cell 15 lines were obtained from American Type Culture Collection (ATCC). SupT11, is a cell line derived from patient NL (Smith et al., 1989, Blood 73:2182-2187). Peripheral lymphocytes were isolated from whole blood by centrifugation on a Ficoll-Hypaque gradient, followed by a one hour adherence in petri 20 dishes to remove the monocytes. Stimulation with phytohemagglutinin (PHA) was carried at a final concentration of 0.1% for 3 days. Patients 62 and 312, presented with T-PLL involving an inversion of chromosome 14, inv(14)(q11;q32.1). In order to determine if the isolated gene is deregulated in 25 cells with the t(14:14)(q11;q32) translocation, we carried out Northern blot analysis comparing the amount of TCL-1 transcript present in resting peripheral blood lymphocytes (PBL), PHA activated PBL, SupT11 cells, a cell line established from a patient with T-ALL with a t(14:14) 30 chromosomal translocation (Lindsay and Bird, 1987, Nature 327:336-338; Bertness et al., 1990, Cancer Genet. Cytogenet. 44:47-54), and in a variety of human cell lines derived from T-cell leukemias (Table 1).

We detected high levels of expression in SupT11 cells 35 (Figure 5A). No expression was detectable in several other tumor derived T-cell lines lacking the TCL-1 translocation, such as Molt 4, HUT78, Jurkat and SupT1 (Figure 5B) (Table 1).

These results were also confirmed by the sensitive assay of RT-PCR as shown in Figure 5C. Of interest is the fact that SupT1 cells carry an inverted chromosome 14, inv 14 (q11;q32), in which the *TCR $\alpha$*  locus is not juxtaposed to the *TCL-1*, but is positioned in front of the immunoglobulin heavy chain locus at 14q32.3 (Baer et al., 1985, Cell 43:705-713). SupT1 cells also carry a translocation between chromosome 7 and 9, that juxtaposes the *TCR $\beta$*  locus to the *TAN-1* oncogene (Ellisen et al., 1991, Cell 66:649-661). Thus an inversion of chromosome 14 that does not involve the *TCL-1* locus is unable to deregulate the *TCL-1* gene. Furthermore we performed a semiquantitative RT-PCR analysis on two independent cases of T-PLL carrying an inversion of chromosome 14, inv(14)(q11;q32). Both cases showed high expression levels of the *TCL-1* gene, comparable to those observed in the SupT1 cell line (Figure 6).

## 7.2. Results

### 7.2.1. Characterization of the *TCL-1* Gene

The *TCL-1* gene is located in a chromosomal region banded by two clusters of breakpoints. In its strategic position, between the two clusters of breakpoints, the *TCL-1* gene becomes juxtaposed to *TCR-C $\alpha$ / $\delta$*  regulatory elements in both types of rearrangements involving 14q32.1. In the case of inversions the *TCL-1* gene is telomeric to the 14q32.1 break, hence the central part of the chromosome between q11 and q32 has flipped upside down and *C $\alpha$ / $\delta$*  has been positioned centromeric and in proximity to the *TCL-1* gene, the same holds true for translocations with inverted duplication. In the case of simple translocations, the gene is centromeric to the breaks and does not move during the rearrangement. In this case the break on the other chromosome 14 occurs in *TCR  $\alpha$ / $\delta$*  locus that moves to a region telomeric to the *TCL-1* gene. In this model of activation the *TCL-1* gene is activated by the control elements of the *TCR* gene, whether they are positioned 5' of the *TCL-1* gene, as in the cases of translocations, or 3' to *TCL-1*, as in the cases of inversions. A similar situation

has been observed in Burkitt's lymphomas, where the Ig enhancers can be located upstream to the MYC oncogene in lymphomas with the t(8;14) chromosomal translocation (Dalla-Favera et al., 1982, Proc. Natl. Acad. Sci. USA 79:7824-7827; Erikson et al., 1986, Science 232:884-886) or downstream to MYC in lymphomas with the t(8;22) or the t(2;8) chromosomal translocation (Croce et al., 1983, Proc. Natl. Acad. Sci. USA 80:6922-6926; Erikson et al., 1983, Proc. Natl. Acad. Sci. USA 80:7581-7585). Similarly Ig enhancers are found downstream to the BCL-2 gene in follicular lymphomas (Tsujimoto et al., 1985, Science 228:1440-1443; Tsujimoto and Croce, 1986, Proc. Natl. Acad. Sci. USA 83:5214-5218) and upstream to the BCL-2 gene in B-cell chronic lymphocytic leukemia (Adachi et al., 1989, Proc. Natl. Acad. Sci. USA 86:2771-2774).

#### 7.2.2. Expression of the TCL-1 Gene in Tumors and Normal Human Tissues

A large number of RNAs from tumor cell lines, both of lymphoid and non-lymphoid origin, were screened to study the pattern of expression of the TCL-1 gene. The results summarized in Table 1 reveal that the TCL-1 gene is expressed at high levels in pre-B cells and in endemic Burkitt's lymphoma cells, which express cell surface IgM and do not secrete Ig (Magrath et al., 1980, J. Natl. Cancer Inst. 64:477-483), but is not expressed in sporadic Burkitt's lymphomas which secrete Ig. This data is illustrated by the presence of TCL-1 transcripts in 697, ALL-1 and BV173 cell lines, all with a pre-B cell phenotype and by its absence in B-lymphoblastoid cell lines such as GM1500 and RPMI 8866. Expression of the TCL-1 gene, at different stages of normal B cell differentiation, was studied by RT-PCR. Fetal bone marrow B-cell subpopulations were isolated by FACS, cDNAs prepared and PCR carried out with a primer from exon 3, p9A, and one from the 3' untranslated region, RevIII, to give a fragment of 270 bp. The results are shown in Figure 6. No signal is present in the CD34+ CD19- stem cell rich fraction. Weak expression appears in CD34+ CD19+ subpopulation of pro B

cells, and expression peaks in IgM<sup>+</sup> pre B cells expressing high levels of CD19. The levels of expression remain high in immature IgM<sup>+</sup> B cells (Figure 7) in the fetal bone marrow, whereas the signal is not detectable in mature peripheral B lymphocytes (Figure 5). No expression of *TCL-1* was observed in myelogenous cell lines or in cell lines derived from gastric, mammary or prostate carcinomas (Table 1). Furthermore no expression of this gene was observed in polyadenylated RNA isolated from a variety of normal human tissues such as heart, brain, placenta, lung, liver, skeletal muscle, kidney and pancreas (Northern blots obtained from Clontech). The results, taken together, suggest that *TCL-1* is expressed specifically in lymphoid cells.

The results suggest that *TCL-1* expression begins in normal B lineage cells as early as the CD34<sup>+</sup>CD19<sup>+</sup> pro B cell stage. Its expression peaks in pre B cells, which express high levels of CD19 but no cell surface IgM, and its expression remains high in immature IgM<sup>+</sup> cells in the bone marrow. A similar pattern of *TCL-1* expression is noted for T lineage cells. Immature thymocytes, including the intermediate CD4<sup>+</sup>/CD8<sup>+</sup> population express *TCL-1* transcripts, whereas mature T cells in circulation do not, unless they are activated, when low levels of *TCL-1* transcripts may be expressed. In contrast mature B cells in the periphery do not express *TCL-1*. These findings parallel the results obtained with the lymphoid cell lines where pro B cell lines with the t(4;11) chromosome translocation failed to express *TCL-1*, while high levels of *TCL-1* transcripts were detected in pre B cell lines. This suggests that expression of *TCL-1* may be linked to immunoglobulin and T cell receptor gene rearrangement and expression. The high level of expression of *TCL-1* in leukemic T cells with the t(14;14) translocation and the inv(14) inversion, but not in leukemic T cell lines with other types of chromosomal rearrangements, strongly supports the conclusion that this gene becomes deregulated as a consequence of its juxtaposition to the  $\alpha/\delta$  locus of the T cell receptor.

### 9. DEPOSIT OF MICROORGANISMS

Plasmid pAll.5, containing a full-length TCL-1 cDNA as an EcoRI insert into the pBluescript SK+ vector (Stratagene); and plasmid p20-7SE, containing a genomic sequence of TCL-1 (including the 5' sequence shown in Figure 3B) as a Sall-EcoRI insert into the pBluescript SK+ vector; were both deposited on October 25, 1994, with the American Type Culture Collection, 1201 Parklawn Drive, Rockville, Maryland 20852, under the provisions of the Budapest Treaty on the International Recognition of the Deposit of Microorganisms for the Purposes of Patent Procedures, and were assigned accession numbers 75923 and 75924, respectively.

The present invention is not to be limited in scope by the specific embodiments described herein. Indeed, various modifications of the invention in addition to those described herein will become apparent to those skilled in the art from the foregoing description and accompanying figures. Such modifications are intended to fall within the scope of the appended claims.

Various publications are cited herein, the disclosures of which are incorporated by reference in their entireties.

CLAIMSWHAT IS CLAIMED IS:

- 5           1. An isolated nucleic acid comprising a nucleotide sequence encoding a TCL-1 protein, wherein the nucleotide sequence is a cDNA sequence.
- 10           2. An isolated nucleic acid of not more than 50 kilobases which contains at least an 18 nucleotide portion encoding a TCL-1 protein fragment.
- 15           3. An isolated nucleic acid of not more than 50 kilobases which contains at least an 18 nucleotide portion of the sequence depicted in SEQ ID NO: 3.
- 20           4. The isolated nucleic acid of Claim 1 comprising the nucleotide sequence of SEQ ID NO:1 from nucleotide number 46 to 387.
- 25           5. An isolated TCL-1 protein.
- 30           6. The TCL-1 protein of Claim 5 having the amino acid sequence of SEQ ID NO: 2 from amino acid number 1 to 114.
- 35           7. A fragment of the protein of Claim 6 which can be specifically bound by an antibody to a TCL-1 protein.
8. An isolated nucleic acid comprising a sequence encoding the fragment of Claim 7.
9. A recombinant DNA vector comprising a nucleotide sequence that encodes a TCL-1 protein, wherein the nucleotide sequence is a cDNA sequence.
10. An host cell that contains the recombinant DNA vector of Claim 9.

11. An antisense molecule comprising a nucleotide sequence complementary to at least a part of the coding sequence of a TCL-1 protein, which is hybridizable to a TCL-1 mRNA.

5

12. An antisense molecule comprising a nucleotide sequence complementary to at least a part of the sequence depicted in SEQ ID NO: 3 which hybridizes to said sequence depicted in SEQ ID NO: 3.

10

13. A fusion protein comprising a TCL-1 protein sequence of at least 10 amino acids linked to a non-TCL-1 protein sequence.

15

14. An antibody which binds to an epitope of a TCL-1 protein.

15. The antibody of Claim 14 which is a monoclonal antibody.

20

16. The antibody of Claim 14 which is a polyclonal antibody.

25

17. A method for producing a recombinant TCL-1 protein comprising:

(a) culturing a host cell transformed with a recombinant expression vector encoding a TCL-1 protein such that the TCL-1 protein is expressed by the cell; and

30

(b) recovering the expressed TCL-1 gene protein.

35

18. An isolated protein comprising an amino acid sequence having at least 70% amino acid sequence identity to the amino acid sequence depicted in SEQ ID NO: 2, over a contiguous sequence of at least 25 amino acids.

19. An isolated protein comprising an amino acid sequence having at least 70% amino acid sequence identity to the amino acid sequence depicted in SEQ ID NO: 2, over a contiguous sequence of at least 50 amino acids.

5

20. Plasmid pA11.5 as deposited with the ATCC and having accession No. 75923.

10

21. Plasmid p20-7SE as deposited with the ATCC and having accession No. 75924.

22. A method for detecting a target sequence indicative of a chromosome 14 abnormality in a sample, comprising the steps of:

15

(a) amplifying the target sequence in the sample using a first primer of 18 to 25 nucleotides complementary to the nucleotide sequence of SEQ ID NO: 1, and a second primer complementary to a region telomeric or centromeric to the *TCL-1* gene; and

20

(b) detecting any resulting amplified target sequence in which the presence of the amplified target sequence is indicative of the abnormality.

25

23. The method of Claim 22 wherein the chromosome abnormality is in the *TCL-1* locus.

24. The method of Claim 22 wherein the chromosome abnormality is a t(14:14)(q11;q32) translocation.

30

25. The method of Claim 22 wherein the chromosome abnormality is a inv(14)(q11;q32) inversion.

35

26. The process of Claim 22 wherein the resultant amplified target sequence is detected using gel electrophoresis.

27. The process of Claim 22 wherein the second primer is a polynucleotide from the T-cell receptor  $\alpha/\delta$  locus.

5 28. The method of Claim 22 wherein the target sequence is amplified using polymerase chain reaction.

10 29. A pharmaceutical composition comprising the antisense molecule of Claim 11 in a pharmaceutically acceptable carrier.

15 30. A pharmaceutical composition comprising the antisense molecule of Claim 12 in a pharmaceutically acceptable carrier.

31. A pharmaceutical composition comprising an antibody of Claim 14 in a pharmaceutically acceptable carrier.

20 32. A method for detecting a target nucleotide sequence indicative of a chromosome 14 abnormality in a nucleic acid sample, comprising the steps of:

25 (a) hybridizing the sample with a nucleic acid probe of not more than 10 kilobases, comprising in the range of 15-1324 nucleotides complementary to the nucleotide sequence of SEQ ID NO: 1; and

(b) detecting or measuring the amount of any resulting hybridization between the probe and the target sequence within the sample.

30 33. The method of Claim 32 wherein the resultant hybridization between the probe and the target sequence within the sample is detected using gel electrophoresis.

35 34. The method of Claim 32 wherein the chromosome 14 abnormality is in the TCL-1 locus.

35. The method of Claim 32 wherein the chromosome 14 abnormality is a t(14:14)(q11;q32) translocation.

5 36. The method of Claim 32 wherein the chromosome 14 abnormality is a inv(14)(q11;q32) inversion.

37. A method for detecting a TCL-1 protein in a patient sample, comprising:

10 (a) contacting the patient sample with an anti-TCL-1 antibody under conditions such that immunospecific binding can occur, and  
(b) detecting or measuring the amount of any immunospecific binding by the antibody.

15 38. The method of Claim 37 wherein the TCL-1 protein is human.

39. The method of Claim 37 that is a Western blot.

20 40. The method of Claim 37 that is an enzyme linked immunosorbent assay.

41. The method of Claim 37 that is an *in situ* hybridization assay.

25 42. The method of Claim 37 that is an immunoprecipitation.

30 43. A diagnostic kit comprising, in a container a compound comprising a probe of not more than 10 kilobases and comprising in the range of 15-1324 nucleotides of the nucleotide sequence of SEQ ID NO:1 or its complement.

35 44. A diagnostic kit comprising in one or more containers, a pair of primers, each having at least 15-25 nucleotides, in which at least one of said primers is hybridizable to SEQ ID NO: 1 or its complement and

wherein said primers are capable of priming DNA synthesis in a nucleic acid amplification reaction.

5           45. The kit of Claim 44 in which one of said primers is hybridizable to a DNA sequence located telomeric or centromeric to the *TCL-1* gene.

10           46. A method for treating a disease state associated with a chromosome 14 abnormality in mammal suffering from a disease state associated with a chromosome 14 abnormality, comprising administering a therapeutically effective amount of a *TCL-1* antisense molecule to a mammal suffering from a disease state associated with a chromosome 14 abnormality.

15           47. The method of Claim 46 wherein the disease state is a T-cell leukemia or lymphoma.

20           48. The method of Claim 46 wherein the chromosome abnormality is a *t*(14:14)(q11;q32) translocation or an *inv*(14)(q11;q32) inversion.

          49. The method of Claim 46 wherein the mammal is a human.

25           50. A method for treating a disease state associated with a chromosome 14 abnormality in mammal suffering from a disease state associated with a chromosome 14 abnormality, comprising administering a therapeutically effective amount of an anti-*TCL-1* antibody to a mammal suffering from a disease state associated with a chromosome 14 abnormality.

30           51. The method of Claim 50 wherein the anti-*TCL-1* antibody is a monoclonal antibody.

52. The method of Claim 50 wherein the disease state is a T-cell leukemia or lymphoma.

5 53. The method of Claim 50 wherein the chromosome abnormality is a t(14:14)(q11;q32) translocation or an inv(14)(q11;q32) inversion.

10 54. The method of Claim 50 wherein the mammal is a human.

15 55. An isolated oligonucleotide having in the range of 15-25 nucleotides which is hybridizable to a DNA molecule, said molecule comprising at least one *TCL-1* exon or its complement.

20 56. An isolated oligonucleotide having in the range of 15-25 nucleotides which is hybridizable to a DNA molecule, said molecule comprising the sequence shown in SEQ ID NO: 3 or its complement.

25 57. A method of diagnosing a T-cell malignancy associated with a chromosome 14 abnormality in a patient comprising detecting said chromosome 14 abnormality according to the method of 22 or 32, in which the presence of the amplified target sequence indicates the presence of a T-cell malignancy in the patient.

30 58. A method of diagnosing a T-cell malignancy associated with a chromosome 14 abnormality in a patient comprising detecting increased expression of a *TCL-1* protein in a sample from the patient, in which an increase in a *TCL-1* protein relative to the level found in an analogous sample from a normal individual, indicates the presence of a T-cell malignancy in the  
35 patient.

59. The method of Claim 58 in which the increased expression of the TCL-1 protein is measured by immunoassay.

5 60. The method of Claim 59 in which the immunoassay is an enzyme linked immunosorbant assay.

61. The method of Claim 58 in which the increased expression of the TCL-1 protein is measured by in situ hybridization.

10

62. The method of Claim 57 or 58 in which the T-cell malignancy is a T-cell leukemia.

15 63. An isolated nucleic acid of not more than 10 kilobases hybridizable under stringent conditions to the sequence shown in SEQ ID NO: 1 or its complement.

20 64. An isolated nucleic acid of not more than 50 kilobases which contains at least an 18 nucleotide portion of the sequence depicted in SEQ ID NO: 5.

25 65. An isolated oligonucleotide having in the range of 15-25 nucleotides which is hybridizable to a DNA molecule, said molecule comprising the sequence shown in SEQ ID NO: 5 or its complement.

# INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US95/13663

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : Please See Extra Sheet.

US CL : Please See Extra Sheet.

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 536/23.1, 23.5; 530/300, 350, 387.1, 388.1; 435/6, 7.1, 69.1, 91.2, 172.3, 240.1, 252.3, 320.1; 514/44, 424/130.1

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, STN, MPSRCH  
TCL(W)1, TCL1, SEQ ID NOS 1, 3, 5

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	Proceedings of the National Academy of Sciences USA, Volume 90, issued 20 October 1993, L. Virgilio et al, "Chromosome walking on the TCL1 locus involved in T-cell neoplasia", pages 9275-9279, see entire document.	11 and 12
Y	WO, A, 93/13119 (BRIGHAM AND WOMEN'S HOSPITAL) 08 July 1993, Figure 4	2, 3, 8, 11, 29, 64, and 65
Y	WO, A, 93/16178 (THE SECRETARY, DEPARTMENT OF HEALTH AND HUMAN SERVICES) 19 August 1993, pages 132, 247, 286, and 328; SEQ ID NOS 856, 1098, 131, and 1362.	2, 3, 8, 11, 29, 64, and 65

☒ Further documents are listed in the continuation of Box C.

☐ See patent family annex.

\* Special categories of cited documents:

\*A\* documents defining the general state of the art which is not considered to be of particular relevance

\*E\* earlier documents published on or after the international filing date

\*L\* documents which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

\*O\* document referring to an oral disclosure, use, exhibition or other means

\*P\* document published prior to the international filing date but later than the priority date claimed

\*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

\*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

\*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

\*Z\* documents member of the same patent family

Date of the actual completion of the international search

26 JANUARY 1996

Date of mailing of the international search report

14 FEB 1996

Name and mailing address of the ISA/US  
Commissioner of Patents and Trademarks  
Box PCT  
Washington, D.C. 20231

Facsimile No. (703) 305-3230

Authorized officer

JAMES MARTINELL

Telephone No. (703) 308-0196
